EXECUTIVE SUMMARY

The U.S. Air Force (USAF), under the Installation Restoration Program (IRP), has conducted a remedial investigation (RI) at Galena Airport (formerly Galena Air Force Station). Within the framework of the IRP, the objective of the RI is to evaluate past hazardous waste disposal and spill sites at Galena Airport. The RI determines the nature and extent of possible contamination, identifies site physical characteristics that may affect contaminant distribution, and defines possible migration pathways.

A baseline risk assessment (BRA) was conducted to support the RI. The BRA determines the potential threat (if any) to human health and/or the environment attributable to the sites under investigation. Remedial actions will be developed for sites that pose an unacceptable threat to either human health or the environment.

ES.1 Background

Volumes 1-3 of this BRA report describe the environmental setting in the vicinity of Galena Airport, document the methods used to evaluate risk, and present the results of the risk assessment for three IRP sites at Galena Airport:

- 1. The Fire Protection Training Area (FPTA);
- 2. The POL Tank Farm; and
- 3. The West Unit.

The BRA was performed for these three sites using data from field investigations conducted during 1992, 1993, and 1994.

This addendum (Volume 4) presents an assessment of the current and possible future risks to human health and the environment

potentially attributable to two additional IRP sites at Galena Airport:

- 1. The Southeast Runway Fuel Spill; and
- 2. The Control Tower Drum Storage Area, South (CTDSA).

The RI was completed for these two sites after additional field investigations were conducted during the summer of 1995.

ES.2 Human Health Assessment

The overall strategy for the human health assessment as well as the technical approach used for individual steps conform to U.S. Environmental Protection Agency (USEPA) recommendations (USEPA, 1989). Risks were evaluated for a range of potentially exposed human populations, including on-base residents, off-base (Galena) residents, on-base workers, and on-base boarding school students (hypothetical). The results of the human health assessment are presented as cancer risk estimates (an estimate of the incremental probability of developing cancer) and noncancer hazard indices (the ratio of an estimated exposure level to a level considered unlikely to cause adverse effects, summed for all chemicals with similar toxic endpoints).

For carcinogenic effects, the USEPA Superfund site remediation goal set forth in the National Contingency Plan (NCP) designates a cancer risk of 10⁻⁴ (1 in 10,000) to 10⁻⁶ (1 in one million). This range is designed to be protective of human health and to provide flexibility for consideration of other factors in risk management decisions. A cancer risk of 1 in one million is considered the *de minimis*, or a level of negligible risk. A cancer risk higher than 1 in one million is not necessarily considered

unacceptable. The State of Alaska plans to use a cancer risk level of 10^{-5} (1 in 100,000) in making risk management decisions (USAF, 1996b). For noncarcinogenic effects, the Superfund site remediation goal is a total hazard index (HI) of 1 for chemicals with similar toxic endpoints.

Of the numerous chemicals detected in environmental media at the two sites, only one chemical poses an estimated risk in excess of 1 in one million: beryllium in groundwater at the Southeast Runway Fuel Spill site. Estimated noncancer HIs are below 1, the Superfund site remediation goal for noncarcinogens, for all scenarios at both sites. An evaluation of combined impacts indicates that combining scenarios (e.g., child and adult), or adding individual site contributions to media at the same location, does not substantially increase the estimated cancer risks or noncancer HIs.

Risks associated with residual petroleum at the sites are addressed by quantifying risks for individual chemicals that are components of the residual petroleum. The results of the risk assessment can be used to evaluate the need to remediate diesel range organics (DRO) and gasoline range organics (GRO), but are not intended to be used to establish alternate cleanup levels for DRO and GRO. Remediation issues related to DRO, GRO, and free product are to be addressed outside the risk assessment.

Southeast Runway Fuel Spill Site

Estimated incremental cancer risks for all scenarios except the current and future Old Town Galena residents are below 1 in one million, considered the *de minimis*, or level of negligible risk. Estimated risks for the current Old Town Galena resident range from an average of 3 in one million to a reasonable maximum of 3 in 100,000 for an adult and from 4 in one million to 1 in 100,000 for a child. These

risk estimates are within the Superfund risk range goal for carcinogens of 1 in 10,000 to 1 in one million. Estimated risks for the future Old Town Galena resident range from an average of 3 in 100,000 to a reasonable maximum of 2 in 10,000 for an adult and from 2 in 100,000 to 3 in 100,000 for a child. The reasonable maximum estimate for the adult exceeds the high end of the Superfund risk range goal.

In the current Old Town Galena resident scenario, ingestion of fruits and vegetables that take up beryllium from the shallow groundwater (either through irrigation or subirrigation) at the location of the gardens southwest of the site contributes the majority of the risks (97%) in all cases. Risks associated with exposure to all other chemicals are negligible. Likewise, in the future Old Town Galena resident scenario, 99% of the estimated risk in all cases is attributable to beryllium in groundwater. Ingestion of groundwater containing beryllium contributes most (85-95%) of the estimated risk; ingestion of fruits and vegetables that take up beryllium from the shallow groundwater (either through irrigation or subirrigation) at gardens in Old Town Galena contributes risks that exceed 1 in one million in some cases. Again, risks associated with exposure to all other chemicals are negligible.

Beryllium is a chemical of potential cancer in groundwater at the site because the background comparison concluded that average beryllium concentrations in groundwater at the site exceeded average beryllium concentrations in background groundwater. However, the level of confidence in this conclusion is rated as weak, based on the p-value of the comparison (0.0630). Moreover, the maximum detected concentration in groundwater at the site (0.00394 mg/L) is lower than the calculated background upper tolerance limit (UTL) for beryllium in groundwater (0.005 mg/L). It is also lower than the USEPA maximum contaminant level (MCL)

and maximum contaminant level goal (MCLG) for drinking water, which are both 0.004 mg/L. There is no reason to suspect that concentrations of beryllium in groundwater at this site might be elevated above background; although beryllium and beryllium alloys are sometimes used for various types of instrument springs, control parts, valves, and airplane carburetors and instruments, it is unlikely that these possible uses have resulted in elevated beryllium concentrations in groundwater at this site. Therefore, the estimated risks associated with exposure to beryllium at this site are probably no higher than risks from exposure to background concentrations of beryllium.

Moreover, the methodologies used to model the migration of beryllium in the groundwater from the Southeast Runway Fuel Spill site to Old Town Galena, and to estimate uptake by fruits and vegetables from groundwater, are conservative (i.e., health protective). groundwater modeling accounted only for horizontal dispersion. Vertical dispersion was ignored. The "source" was defined as 100 ft long with a concentration of 0.00394 mg/L (the maximum detected concentration). As a result, the modeled concentration at Old Town Galena (0.00113 mg/L) is higher than that detected at two of the four monitoring wells located at the site.

To calculate uptake by fruits and vegetables grown in gardens southwest of the site and in gardens in Old Town Galena, it was assumed that 100% of water required by the plants is supplied by shallow groundwater, either through irrigation or subirrigation. The depth of the groundwater fluctuates from very close to the surface to 15 to 20 ft below surface over the course of the year. It is unlikely that the roots of garden plants are in direct contact with the groundwater (and thus are subirrigated) for a substantial portion of the growing season. It is

more likely that precipitation and irrigation water from sources other than the shallow groundwater supply some or all of the water required.

Finally, most residents of Old Town Galena have drinking water trucked in from the city well in the New Town area, upgradient from Galena Airport. There are, however, at least seven private wells still in use in Old Town Galena (USAF, 1995b). Four of these wells, all less than 60 ft deep, were sampled in 1992 and 1993 as part of the RI. Results from beryllium were reported as not detected (ND); however, the detection limit was 0.002 mg/L.

If, as the evidence suggests, beryllium is not elevated above background in the groundwater at the Southeast Runway Fuel Spill site and it is removed as a chemical of potential concern, the risks posed by the site are negligible for all human populations that might encounter site-related contaminants. Estimated risks associated with exposure to beryllium in the groundwater downgradient from the site are not significantly different from exposure to background concentrations of beryllium in the groundwater. On the basis of the results of the human health assessment, remedial action at the Southeast Runway Fuel Spill site is not warranted.

Control Tower Drum Storage Area, South

The estimated incremental cancer risks for all other scenarios at the CTDSA are below 1 in one million. Estimated noncancer HIs are below 1 for all scenarios. On the basis of the results of the human health assessment, remedial action at the CTDSA is not warranted.

ES.4 Ecological Assessment

Ecological risk assessment is defined as a process that evaluates the likelihood that adverse ecological effects may occur, or are occurring, as a result of exposure to one or more stressors (e.g., chemical contaminants). The methodology used to conduct the ecological assessment conforms to USEPA guidance (USEPA, 1992b). An in-depth ecological assessment problem formulation was completed for the Galena Airport (USAF, 1995e) prior to conduct of the ecological assessment.

Species evaluated for assessment of terrestrial ecosystems included terrestrial invertebrates, the American robin, the American kestrel, the meadow vole, and the red fox. These species represent several trophic levels in a terrestrial environment and include several upper trophic level species (kestrel and fox). Aquatic invertebrates and the spotted sandpiper, which feeds on aquatic invertebrates, were selected to evaluate the semiaquatic ecosystem (mudflats) at the edge of the Yukon River. The northern pike, a species of fish that is present in the Galena area for most of the year, represented the aquatic ecosystem in the Yukon River. Pike is not a migratory species, as are species of salmon that are present in the Galena area for only short periods of time.

The "quotient method" (Barnthouse et al., 1982; Urban and Cook, 1986) was used to arithmetically compare a toxicity benchmark (TB) concentration (the measurement endpoint) with the chemical-specific intake for each assessment endpoint species. An ecological quotient (EQ) is calculated by the general form:

EQ = Intake (mg/kg-day)/TB (mg/kg-day).

The TB is a reasonable estimate of a contaminant concentration that may result in adverse effects to an assessment endpoint species, if exceeded in a given environmental medium.

The results of the quotient method, the EQ values, were placed in three categories as follows:

- EQ < 1. Those contaminants with EQs less than one were assumed to pose no significant adverse ecological impacts;
- 10 > EQ ≥ 1. Contaminants with EQs greater than or equal to 1 and less than 10 were classified as contaminants of possible concern; and
- EQ ≥ 10. Contaminants with EQs greater than or equal to 10 were classified as contaminants of probable concern.

A high EQ does not necessarily mean that the local population of the species evaluated is at risk. Therefore, using the EOs, the ecological significance of potential impacts was also A weight-of-evidence analysis of evaluated. potential effects on assessment endpoint species was conducted by reviewing the physical, chemical, ecological, and toxicological properties of chemicals with EQs above 1. On the basis of both the EQ values and the weight-of-evidence evaluation, each chemical with an EO value greater than 1 was rated for potential to cause local population impacts. This population impacts rating (high, medium, or low) provides the initial guidance for the decision-making process. Table ES-1 summarizes the weight-ofevidence findings for local populations of species evaluated in this assessment.

Southeast Runway Fuel Spill Site

Terrestrial Ecosystem—No EQ values above 1 were obtained in this ERA for the invertebrate, red fox, or kestrel. Results of the risk evaluation for plants were inconclusive, except for lead. Given the extreme conservatism associated with the terrestrial toxicity benchmark, the low EQ (1.02) for plants, the lack of impacts to the higher trophic levels, and the fact that site lead levels are not higher than general

Table ES-1 Summary of Potential for Local Population Impacts

background agricultural levels, adverse effects of lead on terrestrial plants are not expected. Several polynuclear aromatic hydrocarbons (PNAs) were noted in the meadow vole with EOs greater than 1 (benzo(a)anthracene. benzo(a)pyrene, and benzo(g,h,i)perylene). Although all of these EQs were greater than 1, they were also less than 10, and are categorized as indicating possible risk; however, the potential for risk from PNAs in this EQ category is likely to be insignificant because current data indicate that vertebrates metabolize PNAs (Eisler, 1987), or the PNAs remain bound to soil particles in the gastrointestinal tract and therefore are not accumulated (ATSDR, 1993). Owing to the low EQ levels of these PNAs, low concentrations of PNAs when compared with other sites, lack of impact to the red fox, and physical and biological processes that limit the vertebrate toxicity, the effects of PNAs on the mammals in the terrestrial ecosystem are expected to be minimal.

As with the plant toxicity, little soil invertebrate toxicity information was found. Several TBs were identified; however, none of the EQ results were above 1. Additionally, there were no EOs above 1 for the kestrel. For the robin, benzo(b)fluoranthene was the only contaminant evaluated with an EQ above 10 at 10.9. The only other chemical with an EQ above 1 for the robin was bis(2-ethylhexyl)phthalate, with an EQ of 1.09. As described above, the potential for risk from PNAs is likely to be insignificant because current data indicate that vertebrates metabolize PNAs (Eisler, 1987), or the PNAs remain bound to soil particles in the gastrointestinal tract and therefore are not accumulated (ATSDR, 1993). Information is limited on avian PNA toxicity. A "worst case" exposure is represented in this assessment by the TB. The applicability of this exposure route is dependent on several factors, including the form of the PNAs at the Southeast Runway Fuel Spill site and the use of the Southeast Runway Fuel Spill site as a breeding area for avian species. During the yearly flood, soil contaminants such as PNAs could be transported to the surface by the rising

These contaminated surface waters waters. could potentially contact ecological receptors, especially as water accumulates at the dike. The Southeast Runway Fuel Spill site is vegetated with alders and other tall vegetation on the slope of the dike. Perching birds are commonly observed and nesting could occur in this vegetation. Because of the high quality of habitat along the dike, the propensity of birds, possible transport and exposure mechanisms of contaminants to avian receptors, adverse impacts to avian receptors (especially eggs and young birds) could occur; however, the ability of vertebrate systems to metabolize PNAs and the strong adsorption of these compounds to soils limits the exposures and toxicities. Possible impacts on avian receptors at the Southeast Runway Fuel Spill site by PNAs are therefore given a medium rating.

The EQ for bis(2-ethylhexyl)phthalate in the robin was calculated to be 1.09. Bis(2ethylhexyl)phthalate is bioconcentrated and the compound has been observed in invertebrates, fish, and terrestrial organisms; however, accumulation of bis(2-ethylhexyl)phthalate is likely to minimized by metabolism, biomagnification in the food chain is not expected to occur. This has been confirmed by the detection of metabolites in animal tissues (ATSDR, 1991a). Because of the potential for metabolism of bis(2-ethylhexyl)phthalate, lack of adverse impacts to the kestrel, and low EQ in robin. the effects of bis(2ethylhexyl)phthalate to the avian ecosystem at the Southeast Runway Fuel Spill site are expected to be minimal.

This assessment indicates that impacts on perching birds, especially eggs and young, might occur due to the presence of PNAs in the surface soil. However, numerous birds have been noted at the site.

Semiaquatic Ecosystem—Semiaquatic exposures considered groundwater beneath the Southeast Runway Fuel Spill site that potentially could migrate to the Yukon River, where expo-

sure to the aquatic invertebrates and spotted sandpiper potentially could occur. None of the chemicals of potential ecological concern evaluated in this assessment showed an EQ above 1 for the spotted sandpiper. Ambient water quality criteria (AWQC) were used as the measurement endpoints for evaluation of the aquatic invertebrates when they existed. AWQC are highly conservative since they are designed to protect most aquatic life. 2-Methylnaphthalene and fluorene are the only compounds with EQs greater than 1 for the aquatic invertebrate. PNAs vary substantially in their toxicity to aquatic organisms. In general, toxicity and bioconcentration factors tend to increase as molecular weight increases (Eisler, 1987). Fluorene and 2-methylnaphthalene are both low molecular weight PNAs with molecular weight values of 166.2 and 142.2, respectively (ATSDR, 1993), indicating low potential for bioconcentration or toxicity. PNA levels in fish and higher trophic levels are usually low because they are rapidly metabolized (Eisler, 1987). Because of the low potential for bioconcentration or toxicity from low molecular weight PNAs, and the ability of higher trophic levels to metabolize PNAs, the adverse impacts from fluorene and 2-methylnaphthalene are expected to be minimal.

Aquatic Ecosystem—EQs were less than 1 at the aquatic ecosystem (Yukon River) for the northern pike.

Control Tower Drum Storage Area

Terrestrial Ecosystem—Terrestrial receptors were not considered owing to the lack of habitat at the CTDSA.

Semiaquatic Ecosystem—None of the chemicals of potential ecological concern evalu-

ated in this assessment showed an EQ above 1 for the aquatic invertebrate. AWQC were used as the measurement endpoints for these assessment endpoint species when they existed. No dilution or volatility factors were applied to the discharged concentrations. 4.4'-DDE had an EQ value greater than 1(6.03) for the spotted sandpiper, indicating possible risk. There were no other chemicals of potential ecological concern noted to have EQs above 1 for the spotted sandpiper. DDT and its metabolites (DDE and DDD) are organochlorine pesticides that are recalcitrant and lipophilic compounds that can enter the food chain easily and progressively biomagnify to organisms at the top of the food chain, such as fish-eating birds. Because of the extensive past use of DDT worldwide, and the persistence of the compounds, these chemicals are virtually ubiquitous and are continually being transformed and redistributed in the environment. A steady state bioconcentration factor of 12,000 for rainbow trout was applied to estimate the concentration in the aquatic invertebrate as the food for the spotted sandpiper. This value is based on ingestion of fish lower on the food chain and exposure to the surrounding media (i.e., water and sediment) (ATSDR, 1994). An analysis of the intake model for the spotted sandpiper indicates that 99% of the EQ contribution was from invertebrate ingestion and only 1% was from ingestion of water. Organochlorine pesticides such as DDT were used extensively at the Galena Airport for insect The CTDSA does not represent a unique source for DDT and its metabolites.

Aquatic Ecosystem—No chemicals were found to pose risk to the northern pike in the Yukon River.

Section 1 INTRODUCTION

The U.S. Air Force (USAF), under the Installation Restoration Program (IRP), has conducted a remedial investigation (RI) at Galena Airport (formerly Galena Air Force Station), Alaska. Figure 1-1 in Volume 1 shows the location of Galena Airport in Alaska. Within the framework of the IRP, the objective of the RI is to evaluate past hazardous waste disposal and spill sites at Galena Airport. The RI determines the nature and extent of possible contamination, identifies site physical characteristics that may affect contaminant distribution, and defines possible migration pathways.

This baseline risk assessment (BRA) was conducted to support the RI. The BRA determines whether there is a possible threat to human health and/or the environment attributable to the sites under investigation. For sites that pose an unacceptable threat to either human health or the environment, remedial actions will be developed.

1.1 IRP Sites

There are 13 identified IRP sites at the Galena Airport. Figure 1-2 in Volume 1 shows the location of the IRP sites, source areas, and other areas of interest at the installation.

Some sites have been closed or are proposed for closure. A BRA is not scheduled for the following sites at this time:

- SS002 Control Tower Drum Storage Area;
- ST003 Petroleum, oils, and lubricants (POL) Fuel Line Leak;
- ST004 JP-4 Fuel Truck Spill; and
- SS007 Drums, Perimeter Dike.

One site, SS006 Waste Accumulation Area, has been incorporated into the West Unit (ST009).

Three other sites, LF008-Main Landfill, LF011-Alternate Landfill, and LF012-Southwest Runway Dump, will be addressed separately outside the IRP process.

Five sites remain "active" IRP sites:

- FT001 Fire Protection Training Area (FPTA);
- ST005 POL Tank Farm;
- ST009 West Unit;
- ST010 Southeast Runway Fuel Spill; and
- SS013 Control Tower Drum Storage Area, South (CTDSA).

The RI was completed for the FPTA, the POL Tank Farm, and the West Unit after the 1994 field season. The first three volumes of this BRA provide details of the environmental setting in the area of Galena Airport, describe the risk assessment methodology used, and document the results of the risk assessment for the FPTA, the POL Tank Farm, and the West Unit.

Additional sampling and analysis were conducted during the summer of 1995 at the Southeast Runway Fuel Spill site and the CTDSA. This addendum (Volume 4 of the BRA) focuses on the two sites for which the RI was completed in 1995. Figure 1-1 shows the location of the two sites and other sites in the immediate vicinity.

This addendum was prepared separately from the other volumes of the BRA to accommodate differing timelines for making site management decisions. Descriptions of the environmental setting and risk assessment methodology that are provided in the first three volumes are not repeated in this addendum.

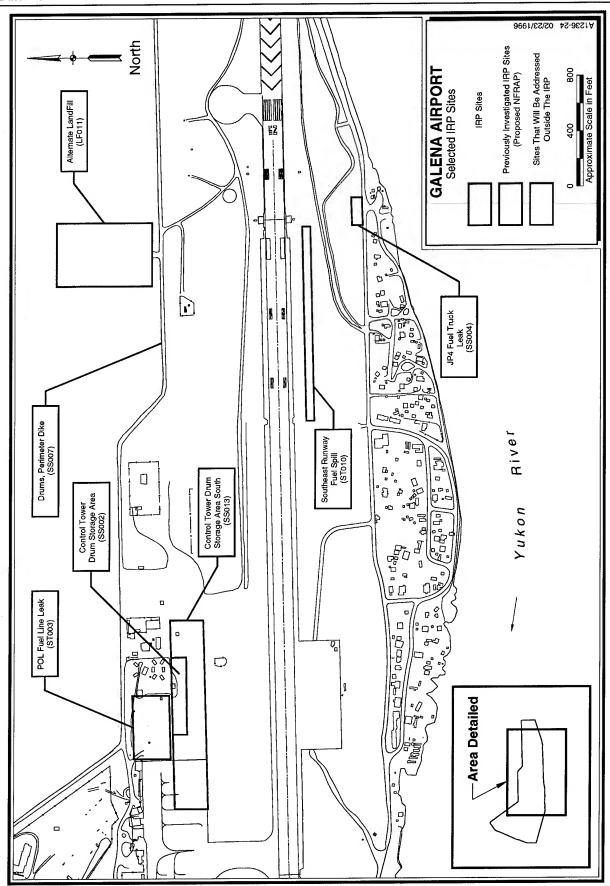

Figure 1-1. Selected IRP Sites, Galena Airport, Alaska

March 1996 1-2

1.2 Purpose and Objectives of the Baseline Risk Assessment

The purpose of this BRA is to identify and characterize the current and potential future threats posed by the sites under investigation to humans living and working in and around Galena Airport and to the ecology of the area. The BRA has three specific objectives:

- 1. To determine the average and reasonable maximum carcinogenic risk (an estimate of incremental risk of developing cancer) to humans attributable to the sites under investigation;
- 2. To characterize the average and reasonable maximum likelihood for noncarcinogenic effects in humans; and
- 3. To evaluate the likelihood that adverse ecological effects may occur.

Average risk is a measure of the central tendency of the risk distribution. The reasonable maximum risk is the highest risk that is reasonably expected to occur.

Within the broader context of the IRP process, the BRA results will be used to make one of the following remedial action recommen-

dations: 1) consider interim remedial action for sites with high current estimated human health risks and/or probable ecological risk; 2) negotiate the need for remedial action for sites with intermediate estimated human health risks and/or possible ecological risk; and 3) pursue no further response action for sites with negligible estimated human health or ecological risks. Section 1.2 in Volume 1 provides a more detailed discussion on how the BRA results are used to support these recommendations.

1.3 Organization of the Baseline Risk Assessment Addendum

This report is organized into six sections. Following the Introduction (Section 1), Sections 2 and 3 each describe the site, summarize data available from the RI, and present the results of the human health and ecological assessments for the Southeast Runway Fuel Spill site and the CTDSA, respectively. Section 4 addresses the potential combined impacts of individual sites and individual scenarios, considering the two sites that are the subject of this addendum, plus the three sites evaluated in Volumes 1-3. Section 5 summarizes conclusions and recommendations. Finally, Section 6 lists references. The appendices supply supporting documentation for the assessments that were conducted.

Section 2 SOUTHEAST RUNWAY FUEL SPILL

Section 2 contains a site-specific BRA for the Southeast Runway Fuel Spill site. Section 2.1 provides a description of the site and Section 2.2 summarizes data evaluation. Section 2.3 presents the human health risk assessment results. Section 2.4 presents the ecological assessment results.

2.1 Site Description

The Southeast Runway Fuel Spill site is located inside of the perimeter dike in a low-lying area just south of the airstrip. It includes a shallow ditch that runs roughly parallel to the runway (Figure 1-1). This is the location of a reported fuel release that occurred during the winter of 1984.

The site is bounded to the north by the runway and to the south by the dike road. The site is vegetated primarily with grass; the state mows the area periodically to keep willows or other tall vegetation from growing too near the runway. Several gardens, maintained by inhabitants of Galena, grow along the southwestern edge of the site. Surface drainage from the ditch flows to the west and accumulates against a dike. In the spring, standing water is common in the lowest portions of the site. Accumulated water evaporates or infiltrates the soil.

The Southeast Runway Fuel Spill site is located entirely within the building restriction line (see Figure 2-2 in Volume 1); therefore, future development/building construction in this area is not possible as long as the airport remains operational.

2.1.1 Sources of Contamination

The site was reportedly contaminated in 1984 from a pipeline leak. During an interview, a Galena resident stated that a spill occurred at this location when the ground was frozen and covered with snow (Danny Patrick, personal communication, 4 October 1992). The source of the spill appeared to be the 4-in.-diameter diesel

pipeline that leads from the barge loading area under the runway to the POL Tank Farm. The spill volume is unknown, but fuel reportedly covered the ground and accumulated in the drainage ditch south of the runway. The accumulated fuel was reported to have been removed from the ground before significant amounts could infiltrate the frozen soil.

The ruptured diesel line was replaced with a 6-in.-diameter diesel pipeline and 8-in.-diameter JP-4 pipeline that were rerouted along the south side of the runway in 1988 (21st Civil Engineering Squadron, drawing no. 86E008, 3 March 1986 with changes made in 1988). The abandoned 4-in.-diameter pipeline was to be removed where it was above ground or interfered with the installation of the new pipeline. Where the old pipeline ran under the runway, it was to be abandoned in place for a distance of 25 ft on either side of the runway shoulder. All piping that was abandoned in place was to be drained, flushed, and capped with ¼-in. steel plates or plugged with concrete.

A barrel dump was also located at the Southeast Runway Fuel Spill site. This dump is noted on the plot plan for the fuel line abandonment and reinstallation project. drums can be seen protruding from the ground at the site. In addition to the fuel line leak and barrel dump, other potential sources of contamination have been identified at the Southeast Runway Fuel Spill site (Assistant Airport Manager Dick Evans, personal communication, 17 July 1995). A tar pit, which has been covered over with soil, was once present at the site, and some patches of tar are still visible at the surface. A building that was located in the area burned down; the contents or purpose of the building is unknown.

A nearby site (JP-4 Fuel Tank leak, SS004), shown in Figure 1-1, was investigated during the Stage 1 RI (USAF, 1989) in response

to an accident that resulted in a POL tank truck releasing approximately 4000 gal. of JP-4 fuel. During that study, petroleum hydrocarbons were detected in the soil. The contaminated soil was removed and no further action was recommended. The JP-4 spill from the tanker did not contribute to the contamination at the Southeast Runway Fuel Spill site.

2.1.2 RI Activities

An investigation was conducted at the Southeast Runway Fuel Spill site during the 1993 and 1995 field seasons. Field screening using soil gas, field infrared (IR) analysis of soils, and laboratory analysis for diesel range organics (DRO) and gasoline range organics (GRO) of direct push technology (DPT) water samples was conducted to determine the extent of fuel contamination at the site. Laboratory confirmation analysis was performed for surface and subsurface soils and groundwater to determine the nature and concentration of site contaminants.

During 1993, field screening was conducted southeast of the main runway to document the presence of hydrocarbons in the soil and to determine the extent of the fuel spill along the ditch. Twenty-four soil vapor samples were collected along the ditch at depths of 5 ft. The samples were analyzed with a photoionization detector (PID) and catalytic hydrocarbon detector (CAT).

On the basis of the results of the soil gas survey, 16 shallow soil samples were collected from locations encompassing the highest soil vapor concentrations and analyzed in the field IR laboratory to determine the presence of hydrocarbons in the soil. Sample results confirmed the east-west extent of contamination found with the soil gas screen.

During 1995, additional investigation activities were conducted at the Southeast Runway Fuel Spill site to confirm the extent of soil contamination and determine the nature of the contaminants and the extent of potential

groundwater contamination. Additional soil gas data were gathered south of the ditch line to help direct sampling activities. On the basis of the soil gas data, DPT water samples were collected and analyzed for DRO. These data were then used to determine the optimum locations of monitoring wells and soil samples.

Three soil borings were sampled at two intervals each along the ditch line. Soil samples were also collected at a depth of 10 to 12 ft below ground level (bgl) from the well bore at three of the four monitoring well locations at the Southeast Runway Fuel Spill site. In addition, a surface soil sample was collected at one of four monitoring well locations. Groundwater samples were collected from all four monitoring wells installed at the site. The analytical results for soil and water samples are presented in Appendix A of the RI report (USAF, 1995b).

2.1.3 RI Conclusions

On the basis of the field screening and laboratory confirmation results, it appears that the reported fuel line rupture occurred near the eastern end of the ditch. Soil contamination due to the fuel leak is limited to the ditch line, and groundwater contamination extends downgradient (south and west) of the ditch. Contaminants of concern include DRO; GRO; and benzene, toluene, ethylbenzene, and xylenes (BTEX) in the immediate vicinity of the leak; however, only DRO were detected any distance from the source. This is consistent with site evidence that indicates reducing conditions near the leak. The high contaminant loading and low permeability in the immediate vicinity of the leak appears to have depleted the available oxygen, limiting the microbial action necessary to break down the BTEX components. Lower concentrations of DRO in the surface soils along the ditch may reflect residual diesel from the spill or the presence of hydrocarbons in runoff from the runway. Although the ground was reportedly frozen at the time of the pipeline rupture, subsurface soil contamination at the western edge of the plume may indicate the

infiltration of fuels flowing along the ditch upon encountering coarser grained soils.

The presence of other site contaminants, such as chlorinated solvents in groundwater and polynuclear aromatic hydrocarbons (PNAs) in soils, are likely to be the result of other sources at the site, such as the drums, the tar pit, or the burned-down building.

2.2 Data Evaluation

Data available from the RI (USAF, 1995b) were used to evaluate human health risks and ecological effects posed by the Southeast Runway Fuel Spill site. Analytical results from a total of four surface soil samples, six subsurface soil samples, and four groundwater samples made up the risk assessment data set. Table 2-1 lists the analytical methods used to test the soil and water samples during the 1995 RI.

Figure 2-1 presents a conceptual diagram for the site from the RI report (USAF, 1995b). This diagram provides a plan view, a geologic cross section, and a table that lists the range of detected concentrations for analytes that have exceeded the RI screening criteria (identified in the key to the figure). The plan view shows the location of all analytical data points (soil samples, monitoring well locations, and DPT water samples). The area of contamination, as determined by soil gas data, is shown on the plan view. The plan view and the geologic cross section can be used in conjunction to provide a three-dimensional visualization of site characteristics and contaminants.

Statistical analyses, in accordance with methods summarized in Section 3 of Volume 1 and described in detail in Appendix A (Volume 2), were conducted on the available data to identify contaminants that were:

- 1. Positively detected in at least one sample in a given medium;
- 2. Detected at levels substantially greater than levels detected in associated blank

samples (at least one result that exceeds the blanks UTL); and

3. Detected at levels elevated above naturally occurring background levels.

Table 2-2 lists the chemicals that were positively detected in the various media at the Southeast Runway Fuel Spill site. These chemicals were subjected to blanks and background comparisons and to additional screening and evaluation for the human health assessment and the ecological assessment before they were identified positively as chemicals of potential concern (COPCs) for human health or chemicals of potential ecological concern (COPECs). Appendix 4A of this volume lists all chemicals that were tested in the various media and indicates, on a medium-specific basis, whether or not there were measurable results after conducting the blanks evaluation and whether or not the average site-related concentration is greater than the average background concentration (metals only).

An evaluation of the adequacy of detection limits was performed by comparing the minimum detection limit for each chemical eliminated as a COPC because it was not detected in a medium with the USEPA Region III residential RBCs. Appendix 4B contains the results of this detection limit screening process. The uncertainties associated with detection limits that are not low enough to detect risk-based concentrations are summarized in Section 2.3.5.

2.3 Human Health Risk Assessment Results

The human health evaluation for the Southeast Runway Fuel Spill site included identification of COPCs (Section 2.3.1), exposure assessment (Section 2.3.2), toxicity assessment (Section 2.3.3), risk characterization (Section 2.3.4), and uncertainty assessment (Section 2.3.5). These tasks were performed according to the methods specified in Section 3 of Volume 1. Section 2.3.6 summarizes conclusions of the human health risk assessment for the site and

recommendations for remedial action based on the risk assessment results.

2.3.1 Chemicals of Potential Concern

Additional screening of the chemicals was performed, in accordance with the methods described in Section 3 of Volume 1, to identify the COPCs carried through the human health assessment. The additional screening involved examining the frequency of detection, evaluating essential nutrients, and comparing maximum detected concentrations with the U.S. Environmental Protection Agency (USEPA) Region III risk-based concentrations (RBCs).

Frequency of Detection

At the Southeast Runway Fuel Spill site, there were no chemicals eliminated from the list of COPCs on the basis of a low (< 5%) frequency of detection.

Essential Nutrients

Essential nutrients that are often present either in the soil and water media were not detected at the Southeast Runway Fuel Spill site at concentrations elevated above background concentrations.

Risk-Based Screening

Maximum detected concentrations of numerous analytes were lower than one-tenth the media-specific USEPA Region III residential RBCs and were eliminated from the list of COPCs. Appendix 4B of this volume contains the risk-based screening results.

COPC Summary

Tables 2-3, 2-4, and 2-5 summarize conclusions for all chemicals that were positively detected in the surface soil, subsurface soil, and groundwater media, respectively, at the Southeast Runway Fuel Spill site. The tables indicate, for each analyte, whether sample concentrations were distinguishable from blank concentrations, whether concentrations were significantly different from background concentrations, whether the chemical was detected in at least 5% of the samples, and whether the chemical was eliminat-

ed as an essential nutrient or by the risk-based screen. Note that since 1993 and later sampling events reported uncensored data (where an ND is reported only if there is no instrument response), very low levels (greater than zero) of many analytes were reported in both blanks samples and site samples. Consequently, many chemicals that are not common field or laboratory contaminants were "detected" in blanks samples and were eliminated as COPCs on the basis of the blanks comparison. No analytes were detected in blanks at concentrations considered to represent a blanks contamination problem requiring corrective action as a result of the data validation process.

Table 2-6 lists the COPCs for the Southeast Runway Fuel Spill site. It includes all chemicals, by medium, with positive results that were greater than background and blank concentrations, that exceeded 5% detection frequency, and that were not eliminated as an essential nutrient or by risk-based screening.

Appendix A of the RI report (USAF, 1995b) provides a complete listing of analytical results from the RI. The appendix reports the sampling location, analytical result, any data qualifiers, and the sample detection limit.

Tables 2-7, 2-8, and 2-9 provide a statistical summary of the values used in the risk assessment for human health COPCs in surface soil and sediments, subsurface soil, and groundwater, respectively. The tables list the detection frequency, maximum detected concentration, mean, standard deviation, and 95% upper confidence limit (UCL) of the data.

2.3.2 Exposure Assessment

Human exposure to COPCs that are present at or migrating from the Southeast Runway Fuel Spill site was assessed in accordance with methods described in Section 3 of Volume 1.

Human Exposure Scenarios

Nine human exposure scenarios were ad-

dressed in the assessment of risks posed by the site:

Current Scenarios (also applicable as future scenarios)

- 1. Short-Term On-Base Resident (subchronic adult only);
- 2. Long-Term On-Base Resident (chronic adult and child);
- 3. Old Town Galena Resident (chronic adult and child);
- 4. New Town Galena Resident (chronic adult and child);
- 5. Short-Term On-Base Worker (subchronic adult only);
- 6. Long-Term On-Base Worker (chronic adult only);
- 7. Construction Worker (subchronic adult only);

Future Scenarios

- 8. Boarding School Student (subchronic/chronic); and
- 9. Old Town Galena Resident (chronic adult and child).

These scenarios are described in Section 3 of Volume 1. Since possible exposures of the Old Town Galena resident might differ in the future if contaminants in the shallow groundwater migrate to the Old Town area, the future Old Town Galena resident is considered separately from the current Old Town Galena resident. The on-base worker scenarios assume that workers at the Southeast Runway Fuel Spill site are engaged in activities outdoors, every work day, for the duration of employment. However, there are no regular employees

in the area of the site. Therefore, the worker scenarios better represent reasonable worst-case exposures that might occur at any time in the future, assuming industrial use of the land involving primarily outdoor work. Owing to the site's location adjacent to the runway, this area will not be frequented by workers or others as long as the airport is actively operating.

Exposure Pathways

Exposure pathways considered for applicability to each Southeast Runway Fuel Spill site exposure scenario included the following:

Soil Pathways

- Incidental ingestion of soil; and
- Dermal contact with soil.

Air Pathways

- Inhalation of fugitive dust; and
- Inhalation of vapors that volatilize from surface and subsurface media.

Groundwater Pathways

- Ingestion of drinking water;
- Dermal contact with water while showering;
- Inhalation of vapors that volatilize from water while showering; and
- Ingestion of plants irrigated or subirrigated with groundwater.

Surface Water Pathways

• Ingestion of fish from the Yukon River.

Groundwater pathways are applicable only if the results of groundwater modeling indicate that contaminants from the Southeast

Runway Fuel Spill site might migrate to Old Town Galena. Surface water pathways are applicable only if the results of groundwater modeling indicate that toxicologically significant concentrations of contaminants originating from the site might reach the Yukon River.

Contaminants detected in the groundwater at the Southeast Runway Fuel Spill site were modeled to Old Town Galena and to the shoreline of the Yukon River. Assuming a generally southwestern flow direction (as determined in the RI), parts of Old Town Galena are directly downgradient of the site.

Concentrations of contaminants in the Yukon River within 5 ft of the shoreline were also estimated, assuming that mixing is limited to river flow within that 5 ft. This assumption was made because there is not instant dilution of contaminants entering the river in the groundwater by the entire volume of river flow that passes by Galena. Rather, a plume would follow the shoreline downstream.

Table 2-10 summarizes the modeled Old Town Galena and river concentrations for the COPCs in groundwater at the Southeast Runway Fuel Spill site. It also lists applicable chemicalspecific fish bioconcentration factors (BCFs) and estimated concentrations in fish exposed to river water within 5 ft of the shoreline. Finally, the table lists the USEPA Region III RBCs for tap water and fish. The estimated fish concentrations are all below the Region III RBCs for fish. The surface water pathways are therefore not quantified for this site. However, modeled concentrations at Old Town Galena of 1,2dichloroethane, benzene, and beryllium exceed one-tenth the Region III tap water RBCs; as such, the groundwater pathways are quantified for the Old Town Galena resident for this site. Since there is no evidence that a groundwater contaminant plume extends from the site to Old town Galena, the groundwater-related exposure pathways are considered possible future exposures and are quantified for the future Old Town Galena resident scenario only.

Also, vegetables grown in gardens located close to the west end of the Southeast Runway Fuel Spill site could possibly be currently taking contaminants directly from the shallow groundwater. Although the water depth fluctuates significantly over the course of a year (from very close to the surface during spring breakup to 15 to 20 ft below the surface at low water), it is unlikely that the roots of the garden plants are in direct contact with the groundwater for a substantial portion of the growing season. Nevertheless, because of the fluctuation in groundwater depth, it is possible that groundwater contamination has affected the soils in which the crops are grown. Therefore, ingestion of plants subirrigated with the shallow groundwater at the location of the gardens located near the site is quantified for the current Old Town Galena resident scenario for this site.

Appendix C (Volume 3) describes the groundwater modeling methodology. Likewise, Appendix D (Volume 3) describes the emissions estimating and air dispersion modeling methodology. These methodologies are not repeated in this addendum. Groundwater modeling results for this site are documented in Appendix 4C of this volume. Appendix 4D of this volume contains dispersion modeling results for this site. Appendices 4E and 4F of this volume describe the methodologies used to model uptake by fruits and vegetables and air concentrations inside a shower stall, respectively, and provide modeling results.

Conceptual Site Model

A conceptual site model presents the current understanding of possible sources of contamination and the likely mechanisms for movement of contamination within and beyond site boundaries. Figure 2-2 is a conceptual site model flow diagram showing the primary sources of contamination at the Southeast Runway Fuel Spill site, their migration pathways, exposure media, and exposure routes that may lead to human exposure. The figure effectively summarizes the results of the human health exposure assessment. It illustrates complete exposure

Comparisons of Southeast Runway Groundwater Modeling Results to USEPA Region III Risk-Based Concentrations (RBCs) **Table 2-10**

pathways for the exposure scenarios that are evaluated and indicates which pathways are quantified for each scenario. It also notes which pathways are possibly complete but probably not significant. These pathways are not quantified.

Quantification of Exposure

Table 2-11 provides a matrix of exposure scenarios and soil-related exposure pathways that are applicable to the Southeast Runway Fuel Spill site and specifies the exposure points and data that were used to derive concentrations in the exposure media at this site. Table 2-12 provides the same information for groundwater-related pathways. Appendix 4G of this volume summarizes the human health exposure point concentrations used to quantify exposure.

Section 3 of Volume 1 describes the methods used to quantify exposure. Human health intake equations and exposure parameters are documented in Appendix 4H of this volume. Intakes were quantified separately for evaluation of carcinogenic and noncarcinogenic effects. Daily intakes for analysis of carcinogenic effects are averaged over a 70-year lifetime. Daily intakes for analysis of noncarcinogenic effects are averaged over the exposure duration only.

2.3.3 Toxicity Assessment

Table 2-13 presents the toxicity values used in the human health risk assessment for COPCs at the Southeast Runway Fuel Spill site. Most of the toxicity values in this table were obtained from USEPA's Integrated Risk Information System (IRIS) in October 1995 or from USEPA's Health Effects Assessment Summary Tables (HEAST) (USEPA, 1994b). Carcinogenic values for some PNAs were calculated using methodologies in provisional guidance for calculating potential potency based on values for benzo(a)pyrene (USEPA, 1993). Although the oral slope factor for benzo(a)pyrene is listed in IRIS, the inhalation slope factor has been withdrawn from IRIS and HEAST. Since there is no inhalation unit risk for benzo(a)pyrene, the USEPA guidance directs that the potential potency values should be applied only to assessment of carcinogenic hazard from oral exposure to PNAs (USEPA, 1993).

The inhalation RfDs for benzene and 1,2-dichloroethane and the inhalation RfD and slope factor for trichloroethene are provisional values recommended by the Superfund Health Risk Technical Support Center (footnoted EPA-ECAO in the USEPA Region III RBC table, USEPA, 1995b). The provisional RfDs and slope factors were converted to RfCs and inhalation unit risk values for use in the risk calculations. The oral slope factor for trichloroethene has been withdrawn from IRIS and HEAST, but is used to evaluate oral exposures to this chemical because no other value is available.

Toxicity values were not available for four COPCs at the Southeast Runway Fuel Spill site. These include lead, benzo(g,h,i)perylene, 2-methylnaphthalene, and phenanthrene. Lead was initially screened using the USEPA-recommended screening level (400 mg/kg) for lead in soil for residential land use (USEPA, 1994d) and the drinking water action level for lead (USEPA, 1994a), and if necessary, evaluated using the USEPA Integrated Exposure Uptake Biokinetic (IEUBK) model for lead in children (USEPA, 1994b). Available health effects information for these COPCs is included in Appendix G (Volume 3), and the impact of the lack of toxicity values for these COPCs is discussed as an uncertainty in Section 2.3.5.

Dermal toxicity values are not listed in Table 2-13. Because of the high level of uncertainty associated with adjusting oral toxicity values (which are generally based on administered dose) to evaluate dermal exposure (which is calculated as an absorbed dose), unadjusted oral values were used to quantify dermal pathway risks. Dermal absorption factors used to quantify dermal contact with soil are listed in Table 2-13. Default values of 1% for inorganic analytes and 10% for organic analytes were used. PNAs were not evaluated for dermal exposure (see discussion in Section 3.1.4 of Volume 1).

Table 2-11

Data Used to Derive Exposure Concentrations in Soil-Related Exposure Media at the Southeast Runway Fuel Spill Site

		Expo	sure Pathways
Exposure Scenario	Ingestion of Soil	Dermal Contact with Soil	Inhalation of Vapor Phase Chemicals and Fugitive Dust in Ambient Air
Current Scenarios			
On-Base Residents -Short Term -Long Term	NA	NA	Modeled concentration of vapor-phase chemicals (D) and wind-blown dust (E) at closest downwind on-base residential receptor.
Galena Residents	NA	NA.	
-Old Town			Modeled concentration of vapor-phase chemicals (D) and wind-blown dust (E) at closest downwind Old Town Galena residential receptor.
-New Town			Modeled concentration of vapor-phase chemicals (D) and wind-blown dust (E) at closest downwind New Town Galena residential receptor.
On-Base Workers			
-Short Term	Surface Soil (A)	Surface Soil (A)	Modeled concentration of vapor-phase chemicals (D) and wind-blown dust (E) directly above the site.
-Long Term	Surface Soil (A)	Surface Soil (A)	Modeled concentration of vapor-phase chemicals (D) and wind-blown dust (E) directly above the site.
-Construction	Mixed Soil (C)	Mixed Soil(C)	Modeled concentration of vapor-phase chemicals (F) and dust generated by construction activity (G) directly above the site.
Future Scenarios			
Boarding School Student	NA	NA	Modeled concentration of vapor-phase chemicals (D) and wind-blown dust (E) at the location of the proposed student dormitory.
Galena Residents			
-Old Town	NA	NA	Modeled concentration of vapor-phase chemicals (D) and wind-blown dust (E) at closest downwind Old Town Galena residential receptor.

Table 2-11 (Continued)

Exposure Media

Remedial Investigation Data:

- (A) Measured concentrations in surface soils, represented by the 95% UCL, or the maximum detected concentration if lower, in soils within 2 ft of the ground surface at the Southeast Runway Fuel Spill site.
- (B) Measured concentrations in subsurface soils, represented by the 95% UCL, or the maximum detected concentration if lower, in soils greater than 2 ft below the ground surface at the Southeast Runway Fuel Spill site.
- (C) Mixed surface and subsurface soil, represented by the highest of either the surface soil concentration (A) or the subsurface soil concentration (B).

Transport and Fate Modeling:

- (D) Estimated concentration of vapor-phase chemicals in ambient air based on emissions from surface soil (A), subsurface soil (B), and dispersion modeling to specific receptor locations.
- (E) Estimated concentration of wind-blown dust based on particulate emissions from surface soil (A) and dispersion modeling to specific receptor locations.
- (F) Estimated concentration of vapor-phase chemicals in ambient air assuming subsurface soil is brought to the surface by construction activities, based on emissions from mixed soils (C) and dispersion modeling to specific receptor locations.
- (G) Estimated concentration of dust generated by construction activities directly above the site, based on particulate emissions from mixed soil (C) and dispersion modeling to specific receptor locations.

NA = Not Applicable

Modeled concentra- tions in fruits and vegetables (E) grown in gardens located in Old Town Galena.

Exposure Media

Remedial Investigation Data:

(A) Measured concentrations in shallow groundwater at the site, represented by the 95% UCL, or the maximum detected concentration, if lower, in groundwater at the four wells located at the Southeast Runway Fuel Spill site. (B) Measured concentrations in shallow groundwater close to the gardens southwest of the site, represented by the highest concentration detected at either MW-03 or MW-04, the two monitoring wells closest to the gardens.

2-26

Table 2-12 (Continued)

Exposure Media (Continued)

Transport and Fate Modeling:

- (C) Estimated concentrations in shallow groundwater at Old Town Galena based on measured concentrations in the groundwater at the site (A) and modeling to the closest downgradient location in Old Town Galena.
- (D) Estimated concentrations in vapor-phase chemicals in the air of a shower stall, assuming use of shallow groundwater (C) as tap water.
- (E) Estimated concentrations in fruits and vegetables grown in home gardens in Old Town Galena, assuming that groundwater (C) provides the sole source of water for the plants, either through irrigation or subirrigation.
- (F) Estimated concentrations in fruits and vegetables grown in gardens southwest of the site, assuming that groundwater (B) provides the sole source of water for the plants, either through irrigation or subirrigation.

^a Absorption factor of 1% was used for inorganic analytes and an absorption factor of 10% was used for organic analytes. PNAs are not evaluated for dermal exposures (see discussion in Section 3.1.4 of Volume 1).

^b U.S. Environmental Protection Agency (USEPA), 1995. Integrated Risk Information System (IRIS). Database search, October 20, 1995.

c Risk from exposure to lead was evaluated using the USEPA IEUBK Model.

U.S. Environmental Protection Agency (USEPA), 1994c. Health Effects Assessment Summary Tables (HEAST) Annual Update, FY 1994. EPA 540-R-020, March 1994.

PNA toxicity values were derived using the Provisional Guidance for Quantitative Risk Assessment of Polycyclic Aromatic Hydrocarbons (EPA/600/R-93/089) dated July 1993.

Value was calculated using the appropriate inhalation reference dose or inhalation slope factor with 20 m³ breathing rate and 70 kg adult body weight. Value was taken from Region III RBC table dated 1/31/95. The table states that this is a provisional value from EPA-ECAO Regional Support.

These values were withdrawn from both IRIS and HEAST. However, Region III recommends using these values in deriving RBCs and they are presented in the Region III RBC table lated 1/31/95. Appendix G (Volume 3) contains toxicological profiles for all of the human health COPCs at the Southeast Runway Fuel Spill site.

2.3.4 Risk Characterization

Carcinogenic risk and noncancer hazard indices (HIs) were estimated for each exposure scenario according to procedures outlined in Section 3 of Volume 1. The carcinogenic risk

and noncarcinogenic risk estimates are presented in Appendix 4J of this volume.

Carcinogenic Effects

For each potentially carcinogenic COPC, the incremental probability that an individual will develop cancer over a lifetime was estimated from projected intake levels and the cancer slope factor or the inhalation unit risk. The USEPA Superfund site remediation goal set forth in the National Contingency Plan (NCP) designates a cancer risk of 10-4 (1 in 10,000) to 10-6 (1 in one million). This range is designed to be protective of human health and to provide flexibility for consideration of other factors in risk management decisions. A cancer risk of 1 in one million is considered the de minimis, or a level of negligible risk, for risk management decisions. A cancer risk higher than 1 in one million is not necessarily considered unacceptable. The State of Alaska plans to use a cancer risk level of 10⁻⁵ (1 in 100,000) in making risk management decisions (USAF, 1996b).

Table 2-14 summarizes the cancer risk estimates for each exposure scenario at the Southeast Runway Fuel Spill site. Estimated incremental cancer risks for all scenarios, except for the current and future Old Town Galena resident, are below 1 in one million. Estimated risks lower than 1 in one million are considered "negligible" and do not warrant remedial action. Estimated cancer risks are 0 for the residents (except Old Town Galena residents) and the boarding school students because inhalation unit risk values are not available for any of the COPCs in soil and inhalation risk could not be calculated. The only applicable exposure path-

way for these scenarios is inhalation of vapors and dust from the soils at the site.

The average and reasonable maximum cancer risk estimates for the current adult Old Town Galena resident are 3 in one million and 3 in 100,000, respectively, and for the current child Old Town Galena resident are 4 in one million and 1 in 100,000, respectively. These risk estimates are within the Superfund risk range goal for carcinogens of 1 in 10,000 to 1 in one million. Ingestion of fruits and vegetables that take up beryllium from the shallow groundwater (either through irrigation or subirrigation) at the location of the gardens southwest of the site contributes the majority of the risks (97%) in all cases. Risks associated with exposure to all other chemicals are negligible.

The estimated risks for the future Old Town Galena resident range from an average of 3 in 100,000 to a reasonable maximum of 2-in 10,000 for an adult and from 2 in 100,000 to 3 in 100,000 for a child. The reasonable maximum estimate for the adult exceeds the high end of the Superfund risk range goal. The majority of the estimated risk (99%) in all cases is attributable to beryllium in groundwater. Ingestion of groundwater containing beryllium contributes most (85-95%) of the estimated risk; ingestion of fruits and vegetables that take up beryllium from the shallow groundwater (either through irrigation or subirrigation) at gardens in Old Town Galena contributes risks that exceed 1 in one million in some cases. Risks associated with exposure to all other chemicals are negligible.

Risk summary tables for each exposure scenario are provided in Appendix 4J of this volume. The tables detail the cancer risk estimates for each applicable chemical and exposure pathway and show the percent contribution of each chemical and pathway to the total estimated risk.

Noncarcinogenic Effects

To characterize the potential noncancer

Table 2-14
Summary of Carcinogenic Risks^a by Exposure Scenario for the Southeast Runway Fuel Spill Site

Old Town Galena Resident	2E-05	3E-05	3E-05	2E-04

NOTE: risk estimates printed in bold type equal or exceed the Superfund site remediation threshold of 10⁻⁶ (1 in one million) for carcinogens.

March 1996 2-30

^aCarcinogenic risk is expressed as a unitless probability of an individual developing cancer.

^bAge 15-18 (Grades 9-12) for the average case and age 6-19 (Grades 1-12, plus two repeat years) for the reasonable maximum case.

^cCancer risks are 0 because inhalation unit risk values are not available for any of the COPCs in soil. The only applicable pathway of exposure is inhalation of vapors and dust from the soils at the site.

NA = Not Applicable

effects of chemicals, comparisons were made between projected intakes of COPCs over a specified time and toxicity values, primarily oral RfDs and inhalation RfCs. A hazard quotient (HQ), which is the ratio between exposure to a chemical and that chemical's toxicity value, was calculated for each noncarcinogenic COPC and exposure pathway. Chemical-specific HQs were then summed for each COPC and each pathway of exposure to calculate the total HI.

The HI is not a statistical probability of a systemic effect occurring. If the exposure level exceeds the appropriate toxicity value (i.e., the HQ is greater than one), there may be cause for concern. The Superfund site remediation goal for noncarcinogens is a total HI of 1 for chemicals with similar toxic endpoints.

Table 2-15 summarizes the noncancer hazard estimates for each exposure scenario. Noncancer HIs are 0 for all scenarios (except Old Town Galena residents) because none of the COPCs in soil have inhalation RfCs and oral RfDs. The only applicable pathways of exposure for these scenarios are soil-related pathways. The HIs for all scenarios are well below the Superfund site remediation goal of 1 for noncarcinogens, indicating that there is little cause for concern about noncarcinogenic effects.

Noncancer risk summary tables for each exposure scenario are provided in Appendix 4J of this volume. The tables detail the noncancer hazard estimates for each applicable chemical and exposure pathway and show the percent contribution of each chemical and pathway to the total estimated HI.

Effects of Exposure to Lead

The maximum detected concentration of lead at the site is 51 mg/kg in the surface soil. Lead is not a COPC in subsurface soil or groundwater at the site. The maximum soil concentrations are well below the 400 mg/kg recommended screening level for lead in residential soil (USEPA, 1994d), which was derived using the IEUBK lead model (USEPA, 1994b).

Since the soil concentrations are well below the soil screening level, lead was not evaluated further.

Major Factors Driving Estimated Risks

Tables 2-16 and 2-17 present a risk characterization summary for carcinogenic risk estimates and noncarcinogenic hazard estimates, respectively. For each scenario the tables specify the exposure pathways that were quantified, the estimated risks for each case, the chemicals and pathways that are major contributors to the estimated risks, and the primary uncertainties associated with the estimates.

The only chemical and pathway that contribute a chemical- and pathway-specific risk greater than 1 in one million is beryllium in groundwater, via ingestion of groundwater and ingestion of fruits and vegetables that take up beryllium from the groundwater. Beryllium is a COPC in groundwater at the site because the background comparison concluded that average beryllium concentrations at the site exceeded average beryllium concentration in background groundwater. However, the level of confidence in this conclusion is rated as weak, based on the p-value of the comparison (0.0630). Moreover, the maximum detected concentration in groundwater at the site (0.00394 mg/L) is lower than the calculated background upper tolerance limit (UTL) for beryllium in groundwater (0.005 mg/L) (USAF, 1995b). It is also lower than the USEPA maximum contaminant level (MCL) and the Maximum Contaminant Level Goal (MCLG) for drinking water, which are both 0.004 mg/L. There is no reason to suspect that concentrations of beryllium in groundwater at this site might be elevated above background; although beryllium and beryllium alloys are sometimes used for various types of instrument springs, control parts, valves, and airplane carburetors and instruments, it is unlikely that these possible uses have resulted in elevated beryllium concentrations at this site.

Table 2-15
Summary of Noncarcinogenic Hazard Indices^a by Exposure Scenario for the Southeast Runway Fuel Spill Site

	C	hild	A	dult
Scenario	Average	Reasonable Maximum	Average	Reasonable Maximum

Old Town Galena Resident	0.01	0.02	0.003	0.007

NOTE: Hazard indices printed in bold type equal or exceed the Superfund site remediation goal of 1 for non-carcinogens.

NA = Not Applicable

March 1996 2-32

^aNoncarcinogenic hazard is not expressed as a probability of an adverse effect but rather a comparison between exposure and a reference dose (hazard index).

^bAge 15-18 (Grades 9-12) for the average case and age 6-19 (Grades 1-12, plus two repeat years) for the reasonable maximum case.

Noncancer hazard indices are 0 because none of the COPCs in soil are known to have adverse effects by the inhalation or oral routes. The only applicable pathways of exposure are soil-related pathways.

^a Hazard indices printed in bold type equal or exceed the Superfund site remediation goal of 1 for noncarcinogens.

^b Applicable only if the total hazard index exceeds 1.

If, as the evidence suggests, beryllium is not elevated above background in the groundwater at the site and it is removed as a COPC, the estimated cancer risks for scenarios associated with groundwater exposures reduce to less than 1 in one million.

2.3.5 Uncertainty Assessment

The risk characterization results are not fully probabilistic estimates of risk but rather conditional estimates of risk that should be interpreted in light of the considerable number of assumptions required to quantify exposure, intake, and dose-response. Uncertainties associated with identification of COPCs, the exposure assessment, and the toxicity assessment all contribute to the level of confidence that can be placed in the risk characterization results.

In general, risk assessment uncertainty was addressed in the BRA by the following:

- 1. Incorporating both average and reasonable maximum values for input parameters, whenever possible, to provide a
 - range of results rather than a single value;
- 2. Erring on the side of conservatism when defining the reasonable maximum case; and
- 3. Identifying and discussing the major sources of uncertainty and their effect on the risk estimates so that the results can be properly interpreted.

Table 2-18 summarizes the primary sources of uncertainty specific to this assessment and the likely impact on risk estimates.

2.3.6 Conclusions and Recommendations

If the shallow groundwater is not used as tap water and does not provide 100% of the water required by fruits and vegetables consumed by residents, the Southeast Runway Fuel Spill site does not pose an unacceptable health

risk to current on-base residents, Old and New Town Galena residents, workers who spend a majority of the workday outside in the immediate vicinity of the site, or to future boarding school students. Even if the groundwater is used as tap water or subirrigates fruits and vegetables, estimated risks are negligible if beryllium is excluded because its presence is not attributable to the site.

On the basis of the results of the human health assessment, there is no need to propose remedial action at the Southeast Runway Fuel Spill site, unless it is shown that beryllium was contributed to the groundwater by site-related activities.

2.4 Ecological Risk Assessment Results

2.4.1 Site Ecology

Ecological features at the Southeast Runway Fuel Spill site include grass, seasonal standing water, and tall vegetation along the dike. The Southeast Runway Fuel Spill site is a shallow ditch lying between the runway to the north and the perimeter dike to the south (Figure 2-3). The site is vegetated primarily with grass and is mowed periodically to keep willows or other tall vegetation from growing too near the runway; however, alders and willows grow along the slope of the dike. Passerine birds such as robins and sparrows frequent the site, but because of human activity, larger wildlife are not common. Several gardens, maintained by Galena residents, grow along the southwestern edge of the site. In the spring, standing water is common in the lowest portions of the site. Surface water from the ditch flows to the west and accumulates against the dike. Waterfowl have been noted utilizing this surface water. Accumulated water evaporates or infiltrates the soil.

2.4.2 Chemicals of Potential Ecological Concern

As discussed in Section 2.1.1, the area of contamination is at the eastern end of the ditch where the fuel line rupture occurred.

Table 2-18
Summary of the Major Uncertainties Associated with the Risk Estimates

Source of Uncertainty	Impact on Risk Characterization
Chemicals of Potential Concern	
Samples representing site media	Could result in an overestimate or underestimate of risks if the samples do not adequately represent media at the site. However, the number and location of samples collected at the site were sufficient to identify the area of contamination in soils and groundwater and assess the magnitude and extent of contamination. Surface soils, however, were defined as encompassing the top two feet of soil. Since exposures are generally limited to the top several inches, inclusion of the top two feet probably overestimates risk for surface soil pathways.
Analytical methods used to test samples	If the analytical methods used do not apply to some chemicals that are present at the site, risks could be underestimated. Since a full suite of analytical methods was selected to test for chemicals known or suspected to be present at the site, the potential for underestimation is reduced.
Presence of beryllium in groundwater at concentrations elevated above background concentrations	The level of confidence in the statistical conclusion that concentrations of beryllium in groundwater are elevated above background concentrations is weak. The maximum detected concentration of beryllium in groundwater is lower than the calculated background UTL for beryllium in groundwater. There is no known or suspected source for beryllium at this site. As a result, calculated risks associated with exposure to beryllium in groundwater are probably no higher than risks of exposure to background concentrations.
Contamination of blanks	Sporadic presence of chemicals in blanks samples was accounted for in blanks comparison. Blanks data do not indicate extensive field or laboratory contaminants.
Tentatively identified compounds	Tentatively identified compounds were not reported or assessed. Most such chemicals are not known to be highly toxic.
Diesel Range Organics and Gasoline Range Organics	DRO and GRO were not evaluated in the risk assessment as groups of chemicals. The assessment addresses individual chemicals only that were speciated by chemical analysis, which includes many constituent compounds of DRO and GRO. However, some constituent compounds were not on the target analyte list. The majority of the risk associated with exposure to DRO and GRO is probably accounted for in an assessment of individual chemicals.

Table 2-18 (Continued)

Source of Uncertainty	Impact on Risk Characterization				
Chemicals of Potential Concern (Continued)					
Detection Limit Adequacy	The minimum detection limit for a few analytes in groundwater that were eliminated as COPC (because they were not detected) exceeds the USEPA Region III tap water RBCs. These include several PNAs, SVOCs, and VOCs. The same is not true for analytes in the soil (when compared to Region III residential soil ingestion RBCs). If these analytes are in fact present in the groundwater and were contributed to the groundwater by site-related activities, the estimated risks for this site may be underestimated. However, since 1993 and later sampling events reported uncensored data (where an ND is reported only if there is no instrument response), the impact on the risk estimates is minimized.				
Exposure Assessment					
Use of current measured concentra- tions to represent current and future concentrations in the exposure media	Because concentrations of chemicals in the soils and groundwater at the site may decrease over time as the chemicals migrate and/or degrade, risks estimates for the current scenarios do not necessarily represent risks that will occur in the future.				
Inclusion of groundwater pathways	Most Old Town Galena residents have their drinking water trucked in from the New Town area; however, there are at least seven wells still in use in the Old Town area (USAF, 1995b). Use of the shallow groundwater for tap water, therefore, cannot be ruled out. Risks associated with use of the shallow groundwater do not apply to residents who use other sources of water for domestic purposes.				
Groundwater modeling	Results of groundwater modeling are indicative of worst-case concentrations that might reach Old Town Galena and the Yukon River. Impacts are likely overestimated for groundwater pathways.				
Estimation of plant uptake of COPCs from groundwater	Models to estimate plant uptake of chemicals are extremely simplified and could lead to an over- or underestimate of COPC concentrations in fruits and vegetables. Since the shallow groundwater is assumed to provide 100% of the plants' water requirements, either through irrigation or subirrigation, the concentrations in fruits and vegetables are probably overestimated.				
Access to site	Access to the site is open. On-base residents and Galena residents are not restricted from walking on the site. Exposure of a roaming resident was not quantified (see discussion in Section 3 of Volume 1). If a resident spends a significant amount of time in the area of the site, estimated risks for that resident may be underestimated.				

Table 2-18 (Continued)

Source of Uncertainty	Impact on Risk Characterization			
Exposure Assessment (Continued)				
Construction worker scenario	Since construction is unlikely to occur at the site, estimated risks for the construction worker scenario do not represent a current or likely future population. The exposure duration for this scenario is biased high.			
Exposure parameter estimation	The standard assumptions regarding body weight, period exposed, life expectancy, and population characteristics may not be representative of any actual exposure situation. Some assumptions may underestimate risks, but most probably overestimate risk. In some cases, nonstandard assumptions were used for site-specific reasons, such as the reasonable maximum exposure duration of 70 years for Galena residents. The use of a 14-year exposure duration for the boarding school student overstates the likely duration of residence for most students.			
Toxicity Assessment				
Absence of toxicity values for some chemicals detected at the site	Lack of toxicity values may result in underestimation of risk; however, most chemicals that lack toxicity values are not very toxic or carcinogenic. Therefore, the degree of underestimation is probably low.			
Use of unverified toxicity values for some chemicals	Could result in an overestimate of risk. However, chemicals with unverified toxicity values do not contribute significantly to estimated risks at the site.			
Bases for derivation of toxicity values	Some common sources of uncertainty in toxicity values include 1) use of information obtained from dose-response studies conducted in laboratory animals to predict effects that are likely to occur in humans; 2) use of dose-response information from effects observed at high doses to predict adverse health effects that may occur at the low levels to which humans are likely to be exposed in the environment; 3) use of information obtained from short-term exposure studies to predict health effects in humans exposed on a long-term basis; 4) use of toxicity values that have been developed for one route of exposure and employing it under a different exposure route; and 5) use of information gathered in studies using homogeneous animal populations (inbred strains) or health human populations (occupational exposures) to predict the effects that are likely to occur in the general human population.			

2-40

March 1996

Table 2-18 (Continued)

Source of Uncertainty	Impact on Risk Characterization		
Toxicity Assessment (Continued)			
Absence of dermal toxicity values	Unadjusted oral toxicity values were used to evaluate dermal exposures. Since most oral values are based on administered dose and dermal exposure is quantified as an absorbed dose, risks from dermal exposure might be underestimated. PNAs were not evaluated for dermal exposures per USEPA guidance (see discussion in Section 3 of Volume 1). PNAs are associated with neoplasia in a variety of mammalian systems. The inability to quantify risks from dermal exposure to PNAs results in an underestimation of risks for the dermal pathway for PNAs.		
Possible synergistic or antagonistic effects of exposure to multiple chemicals	Unknown impact on risk estimates. Chemical- and pathway-specific risk and hazard quotients are summed to account for possible additive effects.		
Risk Characterization			
Applicability of cancer risk estimation methodology to subchronic exposure durations	The estimated intake for cancer risk estimation is averaged over a 70-year period. Exposure to higher concentrations of potential carcinogens for a short duration of time probably does not have the same effect as exposure to lower concentrations over a long duration.		

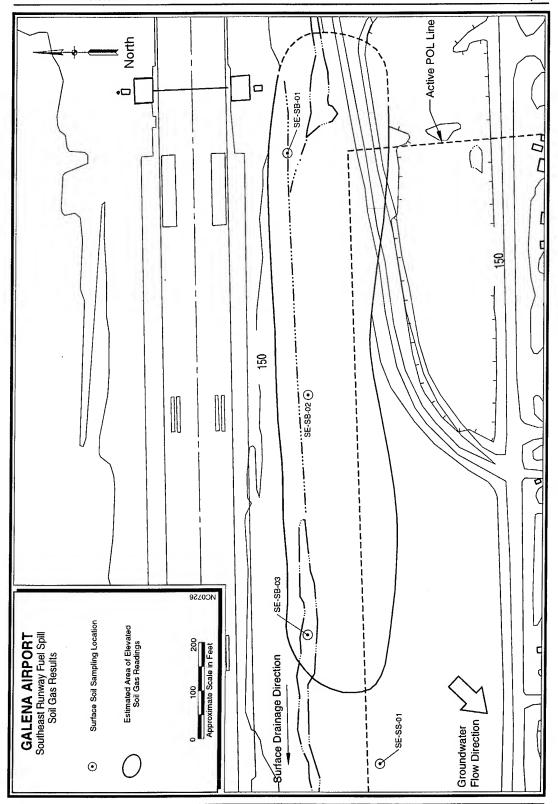

Figure 2-3. Southeast Runway Fuel Spill

Surface water samples were not taken to address the contamination in runoff; however, lower concentrations of petroleum-related compounds have been found in surface soils along the ditch and may reflect residual diesel from spills or runoff from the runway (USAF, 1995b). Surface water is only present a few weeks of the year. Groundwater that discharges to the Yukon River was modeled (see Appendix 4C). COPECs for the Southeast Runway Fuel Spill site are presented in Table 2-19. Section 3.2.2 of Volume 1 details the methods of COPEC identification. COPECs from surface soil were used to address terrestrial receptors, and discharged groundwater COPECs were used to evaluate aquatic and semiaquatic receptors at the shoreline on the banks of the Yukon River. This table includes all chemicals, by medium, that were not eliminated as essential nutrients and with detection results greater than background and blank concentrations.

2.4.3 Exposure Assessment

Figure 2-4 shows the conceptual model for potential receptors and exposure pathways at the Southeast Runway Fuel Spill site. Receptors at the Southeast Runway Fuel Spill site include both terrestrial and aquatic species. Surface soil contamination could affect receptors by contact (ingestion and dermal) with soils and/or ingestion of plants that have taken up the contaminants. Inhalation of vapors and/or fugitive dust also could be a route of exposure. Surface water accumulates against the dike and evaporates or infiltrates the soil. Waterfowl may be present during periods of flooding in this area. Groundwater migration of contaminants to the Yukon River water and shoreline is evaluated for the aquatic and semiaquatic (i.e., shoreline habitats) pathways.

Tables 2-20 and 2-21 list the assessment and measurement endpoints for the Southeast Runway Fuel Spill site. Plants, invertebrates, robin, American kestrel, meadow vole, and red fox represent the terrestrial receptors. Aquatic invertebrates, spotted sandpiper, and northern pike represent the aquatic receptors. Figures 3-5

and 3-6 in Volume 1, Section 3 depict the trophic food chains graphically.

2.4.4 Effects Assessment

Ecological quotients (EQs) were calculated for the assessment endpoint species at the Southeast Runway Fuel Spill site. The results of this evaluation are presented in Table 2-22 for the terrestrial trophic system and Table 2-23 for the aquatic and semiaquatic system. Supporting spreadsheets are presented in Appendix 4M.

2.4.5 Ecological Risk Characterization

Tables 2-24 and 2-25 list the EQ values greater than 1 for the terrestrial and aquatic species, respectively. These tables also provide the order of magnitude of the EQ values (i.e., $1 \le EQ < 10$).

2.4.6 Uncertainty Assessment

Uncertainty occurs in almost every step of the ecological risk assessment (ERA) process. As stated previously, uncertainty is often addressed by making intentionally biased (health-conservative) assumptions so that impacts will not be underestimated. Individual assumptions are therefore conservative, but because of compounded bias the calculated EQs are biased higher than any individual assumption. Table 3-9 in Volume 1, Section 3 lists the uncertainties associated with the ERA, including the Southeast Runway Fuel Spill site. Uncertainties specific to the Southeast Runway Fuel Spill site are listed in Table 2-26.

2.4.7 Conclusions and Recommendations

EQs greater than 1 were noted in each of the trophic pathways. Each pathway is discussed below.

Terrestrial—Mammal (soil → plant → meadow vole → red fox)

Table 2-24 lists the species and order of magnitude of the EQs that exceed 1. Table 2-22 provides a summary of all of the terrestrial EQs calculated. EQs greater than 1 were not noted for the red fox. Adequate toxicity information was found in the literature for the red fox;

Table 2-26 Uncertainties of ERA at the Southeast Runway Fuel Spill Site

Parameter	Assumption	Uncertainty
Pathway: Soil - Plant - Meadow	Vole → Red Fox	
Toxicity Data	Adequate toxicity information was not available to assess impacts to plants. The site visit and modeling of contaminants through the food chain provided the assessment in this ERA for plants.	Impacts to plants could be greater or less than this ERA predicted. The uncertainty would be low-high, bias neutral.
Surface soil exposure	Surface soil samples were taken from 0-2 ft. and composited. This sample is assumed to represent the surface soil available to ecological receptors (Meadow vole).	The method may overestimate exposure concentrations, especially volatiles in the 2 ft anoxic range. The magnitude of the uncertainty would be high, bias high.
Pathway: Soil - Invertebrate - Ro	bin → Kestrel	
Toxicity data	Adequate toxicity data was not available to assess impacts to terrestrial invertebrates. The food chain assessment provided the mechanism for evaluating contaminants through invertebrates.	Impacts to terrestrial invertebrates could be higher or lower. The uncertainty would be low-high, bias neutral.
Use of BCFs or BAFs	BAFs are more representitive of terrestrial bioaccumulation than BCFs; however, when BAFs were unavailable for terrestrial receptors, BCFs were used.	BAFs may be more or less representative of terrestrial bioaccumulation. When a BCF was used, bias would be high because BCFs represent bioconcentration from submersion in the medium. Magnitude of uncertainty would be low.
Pathway: Surface water - Pike		
Groundwater migration	Groundwater beneath the POL migrates and is discharged to the Yukon River where exposure to the pike occurs.	Concentrations were modeled from the POL to the shoreline with no commingling or interferences. The magnitude of the uncertainty would be low, bias neutral.
	Groundwater modeling accurately estimated the concentration of COPECs in the Yukon River.	Dilution factors may not represent conditions in the Yukon. Concentrations may be higher or lower. Magnitude of uncertainty would be low-high, bias neutral.
Assessment endpoint species - Pike	Pike are present in the Yukon River near Galena all year.	Pike are present in the general area but may not be near Galena all year The ERA assumption is conservative, uncertainty would be low, bias high.

Table 2-26 (Continued)

Parameter	Assumption	Uncertainty
Pathway: Surface water → Inver	tebrates - Spotted sandpiper	
AWQC	AWQC are protective of most aquatic life and are conservative measurement endpoints.	AWQC may be more or less conservative than necessary for aquatic invertebrates at the Galena Airport shoreline. The magnitude of the uncertainty would be low, bias high.
Groundwater migration	Groundwater modeling accurately estimated the concentration along the mudflats/shoreline.	No dilution, volatility factors or attenuation was applied to these concentrations. Actual exposure concentrations are likely much lower than predicted. The magnitude of uncertainty would be low, bias high.
Exposure concentration and time	Invertebrates and sandpiper are exposed to the estimated concentrations at the mudflats during entire time species are on site.	Invertebrates may remain in a small geographic area and could be exposed to discharging groundwater continually. However, the spotted sandpiper is mobile and this assumption is highly conservative. The magnitude of uncertainty is low bias high.
	The spotted sandpiper's water intake is 100% from the discharging groundwater.	The spotted sandpiper travels along the shorelines searching for food. To assume that 100% of water intake is from discharging groundwater is highly conservative. The magnitude of uncertainty is low bias high.
Bioavailability of COPECs	All COPECs were assumed to be 100% bioavailable.	Bioavailability changes as physical conditions such as pH or % carbon change. This assumption is conservative. The magnitude would be low-high, bias high.
Bioconcentration factors	Bioconcentration factors (BCF) were applied to estimated invertebrate tissue concentrations of COPECs.	BCFs can vary depending on condition of the study that determined the BCF. Applied to this ERA, they may over or underestimate tissue concentrations. Magnitude of uncertainty is lowhigh, bias neutral.

however, this was not the case with terrestrial plants. Despite searches of the Phytotox Data Base and Hazardous Substance Data Base (HSDB), little applicable information was found; therefore, impacts to plants from soil contaminants at the Southeast Runway Fuel Spill site could not be adequately assessed with the exception of lead. Lead had an EQ of 1.02 in terrestrial plants. The toxicity benchmark (TB) for terrestrial plants was the lowest observed effect concentration (LOEC) that gave a greater than 20% reduction in plant growth. These tests were conducted by amending natural soils with lead to mimic wild conditions (Suter, Will, & Evans, 1993). The fate of lead in soil is dependent on such factors as soil pH, organic matter content in soil, the presence of inorganic colloids and iron oxides, ion-exchange characteristics, and the amount of lead in soil. Lead is strongly sorbed to organic matter in soil, and little is transported into surface water or groundwater. Plants and animals may bioconcentrate lead, but biomagnification has not been detected (ATSDR, 1991b). Although lead is found in most plants and some beneficial applications of lead have been reported, lead is not considered to be an essential element for plants (Demayo, Taylor, Taylor, & Hodson, 1982). At a pH of 4 to 6, the organic lead complexes may become soluble and leach out or may be taken up by plants (ATSDR, 1991b); however, the capacity of soil to bind lead by precipitation, sorption, and chelation indicates that probably very little of the total lead content of soil is available for plant uptake. The ratio of lead concentration in soil water to lead concentration in soil ranges between 0.00003 and 0.0031 depending on the pH, and the humus and clay content of the soil. The total lead content of agricultural soil ranges from 2 to 200 mg/kg with a mean of 16 mg/kg and that of "soluble" lead from 0.05 to 5 mg/kg (Demayo et al., 1982). The 95% UCL of lead in soil at the Southeast Runway Fuel Spill site was 50.8 mg/kg. This value is above the mean value in an agricultural soil, but is well within the range. The TB is based on the soluble form of lead and therefore represents an elevated estimate of exposure to terrestrial plants. There

were no adverse impacts projected to occur in the meadow vole or red fox. Given the extreme conservatism associated with the terrestrial plant benchmark, the low EQ (1.02) for plants and the lack of impacts to the higher trophic levels, and the abundance of healthy and prolific plant life, the effects of lead on plant life at the Southeast Runway Fuel Spill site is expected to be minimal.

Uptake of the contaminants into plants was modeled (see section 3.2.2 of Volume 1 for methodology) to assess intake by the meadow vole. Several PNAs were noted in the meadow with EQs greater than (benzo(a)anthracene, EQ 5.42, benzo(a)pyrene, EO = 1.27. and benzo(g,h,i)perylene, EQ = 5.28). Although EQs between 1 and 10 are categorized as indicating possible risk, the potential for risk from PNAs in this EQ category is likely to be insignificant because current data indicate that vertebrates metabolize PNAs (Eisler, 1987), and the PNAs remain bound to soil particles in the gastrointestinal tract and therefore are not accumulated (ATSDR, 1993). Table 2-27 indicates that between 52% and 78% of the EO was contributed by soil, but it is assumed in the ERA model that 100% of the PNAs are absorbed by the meadow vole. Sorption of PNAs to soil and sediments increases with increasing organic carbon content and is also directly dependent on particle size. Sources of PNAs include petroleum products, wood fires, automotive emissions, and tobacco smoke. PNAs are ubiquitous in soil. Background concentrations for benzo(a)pyrene range from 2 to 1300 μ g/kg in rural soil, 4.6 to 900 μ g/kg in agricultural soil, and 165 to 200 μ g/kg in urban soil (ATSDR, 1993). The 95% UCL of benzo(a)pyrene in soil at the Southeast Runway Fuel Spill site was 496 μ g/kg. This was the highest concentration of the PNAs with EQs greater than 1 at the Southeast Runway Fuel Spill site. This concentration is within the rural and agricultural soil background level.

Table 2-27
Percent Contribution to Meadow Vole and Robin EQs
by Soil and Food Intake

Chemical	EQ	% EQ Soil	% EQ Food
	Meadow	Vole ^a	
Benzo(a)anthracene	5.42	52	48
Benzo(a)pyrene	1.27	70	30
Benzo(g,h,i)perylene	5.28	78	22
	Robin	n b	
Benzo(b)fluoranthene	10.9	27	73
bis(2-Ethylhexyl)phthalate	1.09	0.2	99.8

^a The percent contribution to the EQ by food ingestion for the meadow vole is due to the ingestion of plants.

the ingestion of plants.

b The percent contribution to the EQ by food ingestion for the robin is due to the ingestion of soil invertebrates.

In summary, there appears to be no potential risk to the higher trophic level consumers such as the red fox, and minimal risk to the meadow vole and terrestrial plants at the Southeast Runway Fuel Spill site. Results of the risk evaluation for plants were inconclusive, except for lead. Given the extreme conservatism associated with the terrestrial plant benchmark, the low EQ (1.02) for plants and the lack of impacts to the higher trophic levels, and the site lead level being within the general background agricultural levels, effects of lead to terrestrial plants would be minimal. Several PNAs were noted in the meadow vole with EQs greater than 1 (benzo(a)anthracene, benzo(a)pyrene, and benzo(g,h,i)perylene). Although all of these EQs were greater than 1, they were also less than 10, and are categorized as indicating possible risk; however, the potential for risk from PNAs in this EO category is likely to be insignificant because current data indicate that vertebrates metabolize PNAs (Eisler, 1987), and the PNAs remain bound to soil particles in the gastrointestinal tract and therefore are not accumulated. Owing to the low EQ levels of these PNAs, low concentrations of PNAs when compared with other sites, lack of impact to the red fox, and physical and biological processes that limit the vertebrate toxicity, the effects of PNAs to the mammals in the terrestrial ecosystem are expected to be minimal.

Terrestrial—Avian (soil → invertebrate → robin → kestrel)

Table 2-24 lists the compounds and magnitude of the EQs greater than 1. Earthworm bioaccumulation factors (BAFs) were used to estimate contaminant travel through the terrestrial food chain when they were found in the literature. If earthworm BAFs were not available, then aquatic BCFs were used; however, this probably overestimates the bioaccumulation that occurs in terrestrial systems. When evaluating avian toxicity, only toxicity endpoint data specific to birds were used.

As with the plant toxicity, little soil invertebrate toxicity information was found. Several TBs were identified; however, none of the EQ results were above 1. Additionally, there were no EQs above 1 for the kestrel. For the robin, benzo(b)fluoranthene was the only contaminant evaluated with an EQ above 10 at 10.9. The only other chemical with an EO above 1 for the robin was ethylhexyl)phthalate, with an EQ of 1.09. Benzo(b)fluoroanthene is a PNA, and as described above in the terrestrial mammal section, the potential for risk from PNAs is likely to be insignificant because current data indicate that vertebrates metabolize PNAs (Eisler, 1987), and the PNAs remain bound to soil particles in the gastrointestinal tract and therefore are not accumulated (ATSDR, 1993). Information is limited on avian PNA toxicity. The avian toxicity datum for benzo(b)fluoranthene was a single injection of the compound into a developing chicken embryo; the effect was a decrease in survival. A large uncertainty factor had to be applied to the toxicity data to calculate the TB because of the acute exposure time and the taxonomic differences between the test species and the assessment endpoint species. evidence of avian ingestion of PNAs suggest that a diet containing 4000 mg of PNAs/kg does not cause adverse ecological impacts (Eisler, 1987). The calculated oral intake for the robin at the Galena Airport was 0.0164 mg/kg. There is evidence that embryo toxicity in avian species can be caused by relatively small exposures to PNAs in petroleums (Eisler, 1987). This "worst case" exposure is represented by the TB used in this assessment. The applicability of this exposure route is dependent on several factors, including the form of the PNAs at the Southeast Runway Fuel Spill site and the use of the Southeast Runway Fuel Spill site as a breeding area for avian species. During the yearly flood, soil contaminants such as PNAs could be transported to the surface by the rising waters. These contaminated surface waters could potentially contact ecological receptors, especially as water accumulates at the dike. The Southeast Runway Fuel Spill site is vegetated with alders and other

tall vegetation on the slope of the dike. Perching birds are commonly observed and nesting could occur in this vegetation. Because of the high quality of habitat along the dike, the propensity of birds, possible transport and exposure mechanisms of contaminants to avian receptors, adverse impacts to avian receptors (especially eggs and young birds) could occur; however, the ability of vertebrate systems to metabolize PNAs and the strong adsorption of these compounds to soils limits the exposures and toxicities. Potential impacts to avian receptors at the Southeast Runway Fuel Spill site by PNAs are therefore given a medium rating.

The EQ for bis(2-ethylhexyl)phthalate in the robin was calculated to be 1.09. Bis(2ethylhexyl)phthalate is bioconcentrated and the compound has been observed in invertebrates, fish, and terrestrial organisms; however, accumulation of bis(2-ethylhexyl)phthalate is likely to be minimized by metabolism, biomagnification in the food chain is not expected to occur. This has been confirmed by the detection of metabolites in animal tissues (ATSDR, 1991a). A ringed dove NOAEL (1.11 mg/kg/day) was adjusted to the robin (NOAEL = 1.39 mg/kg/day). No significant reproductive effects were observed among doves on diets containing 10-ppm bis(2-ethylhexyl)phthalate, and the study considered exposure over four weeks and during a critical life stage (Opresko, Sample, & Suter, 1994). The robin intake at the Galena Airport was calculated to be 1.51 mg/kg/day. This level is well below the diet of the doves in the toxicity study. Because of the potential for metabolism of bis(2ethylhexyl)phthalate, lack of adverse impacts to the kestrel, and low EQ in the robin, the effects of bis(2-ethylhexyl)phthalate to the avian ecosystem at the Southeast Runway Fuel Spill site are expected to be minimal.

Aquatic (surface water → pike)

This exposure pathway considered groundwater beneath the Southeast Runway Fuel Spill site that could migrate to the Yukon River, where exposure to the northern pike potentially

could occur. None of the COPECs evaluated in this assessment showed an EQ above 1 for the northern pike. Ambient water quality criteria (AWQC) were used as the measurement endpoints when they existed. AWQC are highly conservative since they are designed to protect most aquatic life.

Semiaquatic (surface water → aquatic invertebrate → spotted sandpiper) Aquatic Invertebrate

This exposure pathway used modeled concentrations of contaminants in groundwater discharging to the surface at the Yukon River shoreline. No dilution or volatility factors were applied to the discharged concentrations. EQs greater than 1 were noted for the aquatic invertebrates and are shown in Table 2-25. Fluorene and 2-methylnaphthalene had EQs above 10 in the aquatic invertebrate. There were no EQs above 1 for the spotted sandpiper. AWQC were used to evaluate impacts to aquatic invertebrates; however, AWQC were not available for 2-methylnaphthalene or fluorene. High uncertainty factors were applied to these TBs since acute LC₅₀ values were used.

2-Methylnaphthalene and fluorene are the only PNAs, and the only organic compounds, with EQs greater than 1 for the aquatic invertebrate. PNAs vary substantially in their toxicity to aquatic organisms. In general, toxicity and bioconcentration factors tend to increase as molecular weight increases (Eisler, 1987). Fluorene and 2-methylnaphthalene are both low molecular weight PNAs, with molecular weight values of 166.2 and 142.2 respectively (ATSDR, 1993). indicating low potential for bioconcentration or toxicity when compared to high molecular weight PNAs. Uptake of PNAs is highly species specific, being higher in algae, molluscs, and other species that are incapable of metabolizing PNAs. There is evidence indicating that age and body size of the invertebrate are important modifiers in PNA accumulation dynamics. PNA levels in fish and higher trophic levels are usually low because they are rapidly metabolized (Eisler, 1987). Because of the low

potential for bioconcentration or toxicity from low molecular weight PNAs, and the ability of higher trophic levels to metabolize PNAs, the adverse impacts from fluorene and 2-methylnaphthalene are expected to be minimal.

In general, ecological risk from contaminants at the Southeast Runway Fuel Spill site is expected to be minimal. PNAs could affect avian reproduction if birds are exposed to the

contaminants during the breeding season. The impacts of PNAs to mammals such as small rodents are expected to be minimal. Impacts to higher trophic levels such as the red fox, kestrel, and spotted sandpiper are not expected to occur. PNAs in the groundwater that may discharge to the shoreline are not expected to affect ecological receptors adversely. The habitat quality at the shoreline is medium to low owing to human activities that limit the potential for exposure.

Section 3 CONTROL TOWER DRUM STORAGE AREA, SOUTH

Section 3 contains a site-specific BRA for the CTDSA. Section 3.1 provides a description of the site and Section 3.2 summarizes data evaluation. Section 3.3 presents the human health risk assessment results. Section 3.4 presents the ecological assessment results.

3.1 Site Description

The CTDSA is a former storage area where spills and regular dumpings occurred from drum handling from the 1940s to the 1960s. As described in the Phase I Records Search Report (USAF, 1985), the site (Spill/Leak No. 1) is an unpaved area located between the runway and apron on which was stored a large number of drums (stacked horizontally about 3 high and 10 wide) containing unused AVGAS, JP-4, JP-1, diesel fuel, solvents, thinners, cooking fuel, and possibly some waste products. Unused drum residues were reportedly dumped on the ground regularly prior to shipping the empty drums off site. Aerial photographs (dating from 1963 to 1971) indicate that the drum-holding area extended from the southeastern quadrant of the present-day air services parking ramp to 600 ft east of the control tower (approximately 500 ft south of the dike road).

The site is situated on level graded gravel fill. Frozen soils were encountered in boreholes from 10 and 30 ft bgl at the eastern and western portion of the site, respectively; however, no permafrost was encountered at the center of the site. Subsurface soils consist of coarse and fine silty sands with traces of natural organic material.

The CTDSA is located almost entirely within the building restriction line (see Figure 2-2 in Volume 1); therefore, future development/building construction in most of this area is not possible as long as the airport remains operational.

3.1.1 Sources of Contamination

The CTDSA was used to store drums as late as the 1970s, as verified by aerial photographs. The presence of contamination is supported by boring logs from the construction of the control tower that document the presence of fuel odor from soil down to the groundwater level (Norman Burgett, personal communication. October 1992). Sampling was performed during the Stage 1 RI (1986 to 1988), but the area investigated did not include the eastern boundary of the storage area as shown in the aerial photographs. The Stage 1 RI did include an area to the north, where 20,000 to 30,000 gal. of diesel fuel was suspected to have been discharged to the ground from a POL fuel line leak (referred to as Spill/Leak No. 2 [ST003]; USAF, 1985).

During the Stage 1 RI, soil samples were collected from 19 borings drilled to the water table (approximately 15 ft below ground surface) and analyzed for total petroleum hydrocarbons (TPH), volatile organic compounds (VOCs), and lead. Low levels of TPH contamination were detected in soils at or near the water table, and BTEX components (< 600 ppb total BTEX) and lead (maximum 59 mg/kg) were also detected in subsurface soil samples. Three monitoring wells were drilled to approximately 30 ft. Groundwater samples were collected and analyzed for petroleum hydrocarbons, purgeable halocarbons and aromatics, and lead. Groundwater samples from all three wells contained low levels of toluene and lead; two wells contained low levels of benzene. Trichloroethene (TCE) was detected in one well at low levels (USAF, 1989).

Also during the Stage 1 RI, a soil gas survey was conducted with a gas chromatograph (GC) to analyze TPH vapors extracted from probes driven into the ground. The highest values were detected at the center and western boundary of the original CTDSA investigation area, where soil gas concentrations were approximately 10 ppmV TPH.

3.1.2 RI Activities

Field investigations conducted at the CTDSA from 1993 to 1995 include a soil gas survey and field TPH screening, collection of groundwater samples from two preexisting monitoring wells, and collection of six surface soil samples. All sample locations are shown in Figure 3-1. The analytical results for soil and water samples are presented in Appendix A of the RI report (USAF, 1995b).

Because the Stage 1 RI did not encompass the entire extent of the former CTDSA, additional field screening was performed in 1993. At 22 locations (in two lines covering the length of the former drum storage area) soil vapor was withdrawn and analyzed with a PID and flame ionization detector (FID). In addition to the soil gas survey, 14 shallow soil samples (5 ft bgl) were collected from within the CTDSA and analyzed for aromatic hydrocarbons (AH) and TPH using the field IR method. Sample locations and soil gas survey results are shown in Figure 3-1.

The 1993 soil gas data from the CTDSA show sporadic high VOC concentrations. The results from the soil TPH/AH screening indicate low to moderate concentrations of hydrocarbons. These data are in agreement with the findings of the Stage 1 RI and may be characteristic of a drum storage area where spills and leaks result in high levels of contamination over a limited areal extent. Hot spots, which may result from these types of releases, were detected at six soil gas sample locations: A-02, A-08, A-11, B-03, B-09, and B-11 (see Figure 3-1).

Six surface soil samples were collected at the CTDSA in 1995 to determine the nature of the soil contamination at the site. The sample locations, shown in Figure 3-1, were chosen from areas of the site that are not being considered for part of a tarmac extension project to be conducted in the near future. Soils that will be covered with pavement will not pose a significant risk to human health or the environment, since the pavement will eliminate dust and

minimize the potential for contaminants to leach into the groundwater.

The surface soil samples were generally made up of gravelly sand fill. No staining or odor was evident in the samples except for the one collected at location 13-SS-06. The soil at this location consisted of gravelly sand fill overlying dark gray-brown silty clay with red mottling and a faint burn odor.

Samples were collected from monitoring wells MW-037 and MW-038 during the 1994 field season. MW-039 was damaged beyond repair and samples could not be retrieved.

3.1.3 RI Conclusions

Data from soil and soil gas screening conducted at the CTDSA in 1993 indicate the presence of limited areas of elevated VOC and TPH concentrations. Laboratory confirmation of surface soil sampling conducted at this site in 1995 indicated the presence of DRO, possibly from motor oil, in excess of the screening criteria. However, no staining or odor was noted at the sampling locations where the detections occurred, and the majority of the soil samples contained little or no detectable DRO. These data are consistent with minor surface soil contamination from small leaks and spills. The Bureau of Land Management (BLM) uses the eastern portion of the site to park aircraft and refueling trucks. Vehicle traffic may also occur at other parts of the site, and small aircraft may taxi through this area as well. Aircraft and vehicle traffic are likely to be sources of DRO at this site.

The Stage 1 RI documented the presence of TCE in groundwater samples from one of the downgradient wells (MW-038). A sample collected from this well in 1994 was found to contain TCE in excess of the 5 μ g/L MCL. It appears that small leaks and spills from drumhandling activities at this site may have resulted in the presence of TCE in the groundwater.

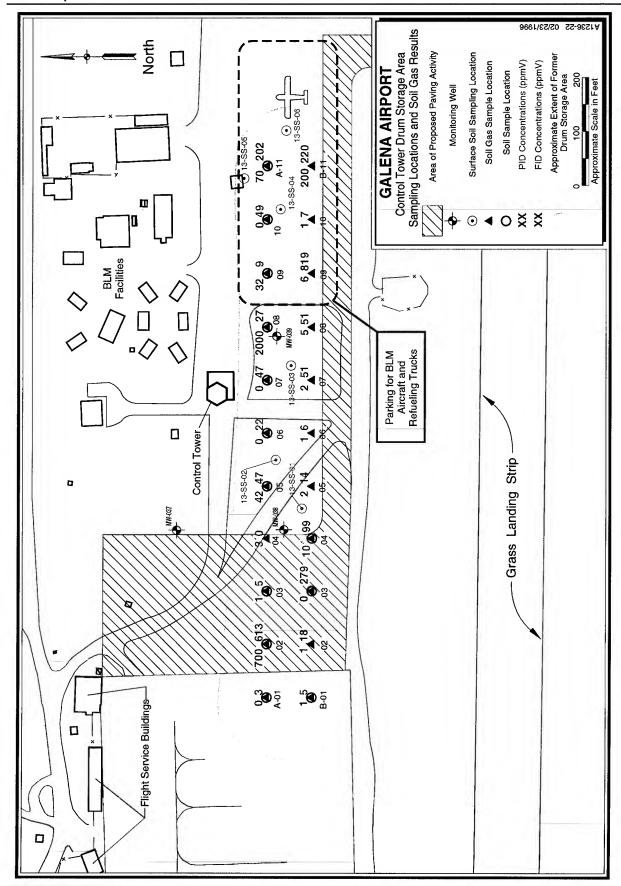

Figure 3-1. Sampling Locations and Soil Gas Survey Results for the Control Tower Drum Storage Area South (SS013)

3.2 Data Evaluation

Data available from the RI (USAF, 1995b) were used to evaluate human health risks and ecological effects posed by the CTDSA. Analytical results from a total of six surface soil samples and two groundwater samples made up the risk assessment data set. Table 3-1 lists the analytical methods used to test the soil and water samples during the 1994-1995 RI.

Statistical analyses, in accordance with methods summarized in Section 3 of Volume 1 and described in detail in Appendix A (Volume 2), were conducted on the available data to identify contaminants that were:

- 1. Positively detected in at least one sample in a given medium;
- Detected at levels substantially greater than levels detected in associated blank samples (at least one result that exceeds the blanks UTL); and
- Detected at levels elevated above naturally occurring background levels.

Table 3-2 lists the chemicals that were positively detected in the various media at the CTDSA. These chemicals were subjected to blanks and background comparisons and to additional screening and evaluation for the human health assessment and the ecological assessment before they were identified *positively* as COPCs for human health or COPECs. Appendix 4A of this volume lists all chemicals that were tested in the various media and indicates, on a medium-specific basis, whether or not there were measurable results after conducting the blanks evaluation and whether or not the average site-related concentration is greater than the average background concentration (metals only).

An evaluation of the adequacy of detection limits was performed by comparing the minimum detection limit for each chemical eliminated as a COPC because it was not detected in a medium with the USEPA Region III

residential RBCs. Appendix 4B contains the results of this detection limit screening process. The uncertainties associated with detection limits that are not low enough to detect risk-based concentrations are summarized in Section 3.3.5.

3.3 Human Health Risk Assessment Results

The human health evaluation for the CTDSA included identification of COPCs (Section 3.3.1), exposure assessment (Section 3.3.2), toxicity assessment (Section 3.3.3), risk characterization (Section 3.3.4), and uncertainty assessment (Section 3.3.5). These tasks were performed according to the methods specified in Section 3 of Volume 1. Section 3.3.6 summarizes conclusions of the human health risk assessment for the CTDSA and recommendations for remedial action based on the risk assessment results.

3.3.1 Chemicals of Potential Concern

Additional screening of the chemicals was performed, in accordance with the methods described in Section 3 of Volume 1, to identify the COPCs carried through the human health assessment. The additional screening involved examining the frequency of detection, evaluating essential nutrients, and comparing maximum detected concentrations with USEPA Region III RBCs.

Frequency of Detection

At the CTDSA, there were no chemicals that were eliminated from the list of COPCs on the basis of a low (< 5%) frequency of detection.

Essential Nutrients

Essential nutrients that are often present either in the soil and water media were not detected at the CTDSA at concentrations elevated above background concentrations.

Risk-Based Screening

Maximum detected concentrations of numerous analytes were lower than one-tenth the media-specific USEPA Region III residential RBCs and were eliminated from the list of

COPCs. Appendix 4B of this volume contains the risk-based screening results.

COPC Summary

Tables 3-3 and 3-4 summarize conclusions for all chemicals that were positively detected in the surface soil and groundwater media, respectively, at the CTDSA. The tables indicate, for each analyte, whether sample concentrations were distinguishable from blank concentrations, whether concentrations were significantly different from background concentrations, whether the chemical was detected in at least 5% of the samples, and whether the chemical was eliminated as an essential nutrient or by the risk-based screen. Note that since 1993 and later sampling events reported uncensored data (where an ND is reported only if there is no instrument response), very low levels (greater than zero) of many analytes were reported in both blanks samples and site samples. Consequently, many chemicals that are not common field or laboratory contaminants were "detected" in blanks samples and were eliminated as COPCs on the basis of the blanks comparison. No analytes were detected in blanks at concentrations considered to represent a blanks contamination problem requiring corrective action as a result of the data validation process.

Table 3-5 lists the COPCs for the CTDSA. It includes all chemicals, by medium, with positive results that were greater than background and blank concentrations, that exceeded 5% detection frequency, and that were not eliminated as an essential nutrient or by risk-based screening.

Appendix A of the RI report (USAF, 1995b) provides a complete listing of analytical results from the RI. The appendix reports the sampling location, analytical result, any data qualifiers, and the sample detection limit.

Tables 3-6 and 3-7 provide a statistical summary of the values used in the risk assessment for human health COPCs in surface soil and groundwater, respectively. The tables list

the detection frequency, maximum detected concentration, mean, standard deviation, and 95% UCL of the data.

3.3.2 Exposure Assessment

Human exposure to COPCs that are present at or migrating from the CTDSA was assessed in accordance with methods described in Section 3 of Volume 1.

Human Exposure Scenarios

Nine human exposure scenarios were addressed in the assessment of risks posed by the CTDSA:

Current Scenarios (also applicable as future scenarios)

- 1. Short-Term On-Base Resident (subchronic adult only);
- 2. Long-Term On-Base Resident (chronic adult and child);
- 3. Old Town Galena Resident (chronic adult and child);
- 4. New Town Galena Resident (chronic adult and child);
- 5. Short-Term On-Base Worker (subchronic adult only);
- 6. Long-Term On-Base Worker (chronic adult only);
- Construction Worker (subchronic adult only);

Future Scenarios

- 8. Boarding School Student (subchronic/chronic); and
- 9. Old Town Galena Resident (chronic adult and child).

Bold numbers indicate the lower value used for the risk assessment, which was the lower of either the UCL or the maximum detected concentration.

^a No toxicity data available.

These scenarios are described in Section 3 of Volume 1. Since possible exposures of the Old Town Galena resident might differ in the future if contaminants in the shallow groundwater migrate to the Old Town area, the future Old Town Galena resident is considered separately from the current Old Town Galena resident. The on-base worker scenarios assume that workers at the CTDSA are engaged in activities outdoors, every work day, for the duration of employment. However, employees in this area work in the control tower itself and do not frequent the grounds outside. Therefore, the worker scenarios better represent reasonable worst-case exposures that might occur at any time in the future, assuming industrial use of the land involving primarily outdoor work.

Exposure Pathways

Exposure pathways considered for applicability to each CTDSA exposure scenario included the following:

Soil Pathways

- Incidental ingestion of soil; and
- Dermal contact with soil.

Air Pathways

- Inhalation of fugitive dust; and
- Inhalation of vapors that volatilize from surface and subsurface media.

Groundwater Pathways

- Ingestion of drinking water;
- Dermal contact with water while showering;
- Inhalation of vapors that volatilize from water while showering; and
- Ingestion of plants irrigated or subirrigated with groundwater.

Surface Water Pathways

Ingestion of fish from the Yukon River.

Groundwater pathways are applicable only if the results of groundwater modeling indicate that contaminants from the CTDSA might migrate to Old Town Galena. Surface water pathways are applicable only if the results of groundwater modeling indicate that toxicologically significant concentrations of contaminants originating from the CTDSA might reach the Yukon River.

Contaminants detected in the groundwater at the CTDSA were modeled to Old Town Galena and the shoreline of the Yukon River. Assuming a generally southwestern flow direction, most of Old Town Galena is not directly downgradient of the CTDSA. However, modeled concentrations at the closest downgradient receptor location in Old Town Galena provide a worst-case estimate of possible impacts on wells that could be located at the extreme western edge of town.

Concentrations of contaminants in the Yukon River within 5 ft of the shoreline were also estimated, assuming that mixing is limited to river flow within that 5 ft. This assumption was made because there is not instant dilution of contaminants entering the river in the groundwater by the entire volume of river flow that passes by Galena. Rather, a plume would follow the shoreline downstream.

Table 3-8 summarizes the modeled Old Town Galena and river concentrations for the COPCs in groundwater at the CTDSA. It also lists applicable chemical-specific fish BCFs and estimated concentrations in fish exposed to river water within 5 ft of the shoreline. Finally, the table lists the USEPA Region III RBCs for tap water and fish. The estimated fish concentrations are all below the Region III RBCs for fish. The surface water pathways are therefore not quantified for the CTDSA. The modeled Old Town Galena concentrations, considered the

Estimated concentration in Yukon River within 5 ft of shoreline, assuming mixing is limited to river flow within that 5 ft.

Fish bioconcentration factor. See Appendix J (Ecological Assessment Toxicity Profiles) of Volume 3 and Appendix 4L of this addendum...

^c Concentration in water (ug/L) x 1 L/kg x 1 mg/1000 ug x BCF (unitless).

Modeled concentration exceeds one-tenth the Region III tap water RBC. This chemical is included in the groundwater pathway calculations. U.S. Environmental Protection Agency (USEPA) Region III, Risk-Based Concentration Table, January-June 1995, March 7, 1995.

NOTE: Shaded values exceed Region III RBC for tap water or fish:

NV = No value

worst-case possible impact on any well located at the western edge of Old Town Galena, are all below the respective Region III tap water RBCs, except for heptachlor epoxide, which only slightly exceeds the tap water RBC. However, since modeled concentrations at Old Town Galena of three chemicals (aldrin, heptachlor epoxide, and TCE) exceed one-tenth the tap water RBC, the groundwater pathways are quantified for the Old Town Galena resident for this site. Since there is no evidence that a groundwater contaminant plume extends from the site to New Town Galena, the groundwater-related exposure pathways are considered possible future exposures and are quantified for the future Old Town Galena resident scenario only.

Appendix C (Volume 3) describes the groundwater modeling methodology. Likewise, Appendix D (Volume 3) describes the emissions estimating and air dispersion modeling methodologies. These methodologies are not repeated in this addendum. Groundwater modeling results for this site are documented in Appendix 4C of this volume. Appendix 4D of this volume contains dispersion modeling results for this site. Appendices 4E and 4F of this volume describe the methodologies used to model uptake by fruits and vegetables and air concentrations inside a shower stall, respectively, and provide modeling results.

Conceptual Site Model

A conceptual site model presents the current understanding of possible sources of contamination and the likely mechanisms for movement of contamination within and beyond site boundaries. Figure 3-20 is a conceptual site model flow diagram showing the primary sources of contamination at the CTDSA, their migration pathways, exposure media, and exposure routes that may lead to human exposure. The figure effectively summarizes the results of the human health exposure assessment. It illustrates complete exposure pathways for the exposure scenarios that are evaluated and indicates which pathways are quantified for each scenario. It also notes which pathways are possibly complete but

probably not significant. These pathways are not quantified.

Quantification of Exposure

Table 3-9 provides a matrix of exposure scenarios and soil-related exposure pathways that are applicable to the CTDSA and specifies the exposure points and data that were used to derive concentrations in the exposure media at this site. Table 3-10 provides the same information for groundwater-related pathways. Appendix 4G of this volume summarizes the human health exposure point concentrations used to quantify exposure.

Section 3 of Volume 1 describes the methods used to quantify exposure. Human health intake equations and exposure parameters are documented in Appendix 4H of this volume. Intakes were quantified separately for evaluation of carcinogenic and noncarcinogenic effects. Daily intakes for analysis of carcinogenic effects are averaged over a 70-year lifetime. Daily intakes for analysis of noncarcinogenic effects are averaged over the exposure duration only.

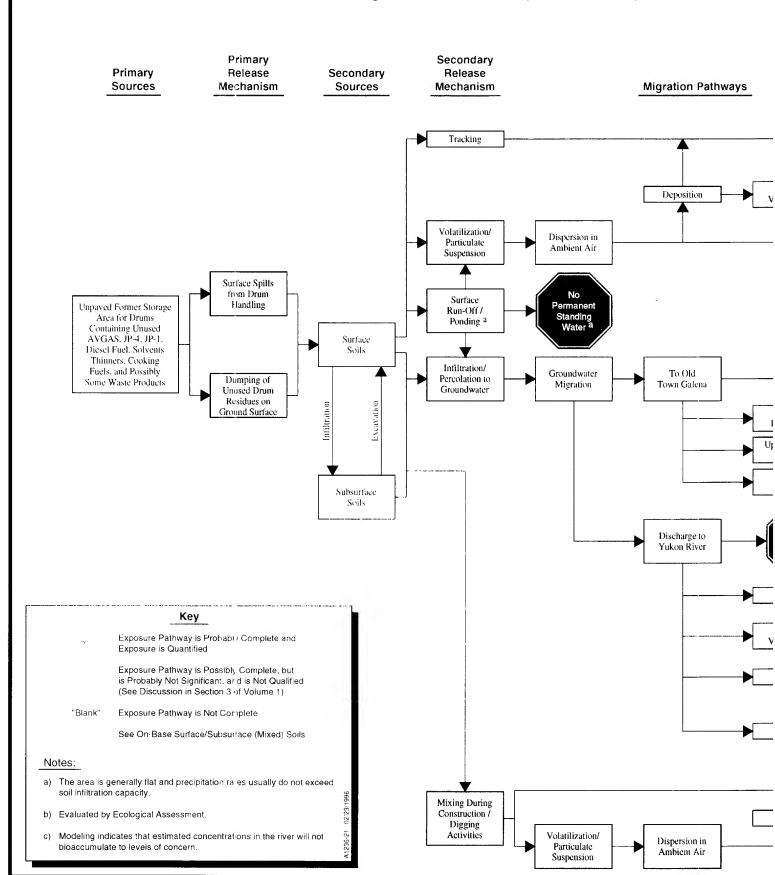

3.3.3 Toxicity Assessment

Table 2-11 presents the toxicity values used in the human health risk assessment for COPCs at the CTDSA. Most of the toxicity values in this table were obtained from IRIS searches conducted in October 1995 or from HEAST (USEPA, 1994b). Carcinogenic values for some PNAs were calculated using methodologies in provisional guidance for calculating potential potency based on values benzo(a)pyrene (USEPA, 1993). Although the oral slope factor for benzo(a)pyrene is listed in IRIS, the inhalation slope factor has been withdrawn from IRIS and HEAST. Since there is no inhalation unit risk for benzo(a)pyrene, the USEPA guidance directs that the potential potency values should be applied only to assessment of carcinogenic hazard from oral exposure to PNAs (USEPA, 1993).

The inhalation RfD for 1,2-dichloroethane and the inhalation slope factor for

Galena Resident -Old Town	Modeled concentrations in groundwater (B) at closest downgradient receptor in Old Town Galena.	Modeled concentrations in groundwater (B) at closest downgradient receptor in Old Town Galena.	Modeled concentrations of vapor phase chemicals (C) in the air of a shower stall.	Modeled concentrations in fruits and vegetables (D) grown in gardens located in Old Town Galena.

Exposure Media

Remedial Investigation Data:

(A) Measured concentrations in shallow groundwater at the CTDSA site represented by the 95% UCL, or the maximum detected concentration if lower, in groundwater at the two wells located at the CTDSA.

Transport and Fate Modeling:

- (B) Estimated concentrations in shallow groundwater at Old Town Galena based on measured concentrations in the groundwater at the CTDSA site (A) and modeling to the closest downgradient location in Old Town Galena.
- (C) Estimated concentrations of vapor-phase chemicals in the air of a shower stall, assuming use of shallow groundwater (B) as tap water.
- (D) Estimated concentrations in fruits and vegetables grown in home gardens in Old Town Galena, assuming that groundwater (B) provides the sole source of water for the plants, either through irrigation or subirrigation.

NA = Not applicable.

TCE are provisional values recommended by the Superfund Health Risk Technical Support Center (footnoted EPA-ECAO in the USEPA Region III RBC table, USEPA, 1995b). The provisional RfD and slope factor were converted to an RfC and inhalation unit risk value for use in the risk calculations. The oral slope factor for TCE has been withdrawn from IRIS and HEAST, but is used to evaluate oral exposures to this chemical because no other value is available.

Toxicity values were not available for four COPCs at the CTDSA. These include lead, benzo(g,h,i)perylene, 2-methylnaphthalene, and phenanthrene. Lead was initially screened using the USEPA-recommended screening level (400 mg/kg) for lead in soil for residential land use (USEPA, 1994d) and the drinking water action level for lead (USEPA, 1994a), and if necessary, evaluated using the USEPA IEUBK model for lead in children (USEPA, 1994b). Available health effects information for these COPCs is included in Appendix G (Volume 3), and the impact of the lack of toxicity values for these COPCs is discussed as an uncertainty in Section 3.3.5.

Dermal toxicity values are not listed in Table 3-11. Because of the high level of uncertainty associated with adjusting oral toxicity values (which are generally based on administered dose) to evaluate dermal exposure (which is calculated as an absorbed dose), unadjusted oral values were used to quantify dermal pathway risks. Dermal absorption factors used to quantify dermal exposures are listed in Table 3-11. Default values of 1% for inorganic analytes and 10% for organic analytes were used. PNAs were not evaluated for dermal exposure (see discussion in Section 3.1.4 of Volume 1).

Appendix G of Volume 1 contains toxicological profiles for all of the human health COPCs at the CTDSA, except antimony. Appendix 4I of this volume contains a toxicological profile for antimony.

3.3.4 Risk Characterization

Carcinogenic risk and noncancer HIs were estimated for each exposure scenario according to procedures outlined in Section 3 of Volume 1. The carcinogenic risk and noncarcinogenic risk estimates are presented in Appendix 4J of this volume.

Carcinogenic Effects

For each potentially carcinogenic COPC, the incremental probability that an individual will develop cancer over a lifetime was estimated from projected intake levels and the cancer slope factor or the inhalation unit risk. The USEPA Superfund site remediation goal set forth in the NCP designates a cancer risk of 10⁻⁴ (1 in 10,000) to 10⁻⁶ (1 in one million). This range is designed to be protective of human health and to provide flexibility for consideration of other factors in risk management decisions. A cancer risk of 1 in one million is considered the de minimis, or a level of negligible risk, for risk management decisions. A cancer risk higher than 1 in one million is not necessarily considered unacceptable. The State of Alaska plans to use a cancer risk level of 10⁻⁵ (1 in 100,000) in making risk management decisions (USAF, 1996b).

Table 3-12 summarizes the cancer risk estimates for each exposure scenario at the CTDSA. Estimated incremental cancer risks for all scenarios are below 1 in one million. Estimated risks lower than 1 in one million are considered "negligible" and do not warrant remedial action.

Risk summary tables for each exposure scenario are provided in Appendix 4J of this volume. The tables detail the cancer risk estimates for each applicable chemical and exposure pathway and show the percent contribution of each chemical and pathway to the total estimated risk.

Noncarcinogenic Effects

To characterize the potential noncancer effects of chemicals, comparisons were made

Toxicity Values for Control Tower Drum Storage Area, South COPCs Table 3-11

Absorption factor of 1% was used for inorganic analytes and an absorption factor of 10% was used for organic analytes. PNAs are not evaluated for dermal exposures (see discussion in Section 3.1.4 of Volume 1).

Risk from exposure to lead was evaluated using the USEPA IEUBK model.

USEPA, 1995. Integrated Risk Information System (IRIS). Database search, October 20, 1995.

⁴ PNA toxicity values were derived using the Provisional Guidance for Quantitative Risk Assessment of Polycyclic Aromatic Hydrocarbons (EPA/600/R-93/089) dated July 1993 ^eUSEPA, 1994c. Health Effects Assessment Summary Tables (HEAST) Annual Update, FY 1994. EPA 540-R-020, March 1994.

Value was taken from Region III RBC table dated 1/31/95. The table states that this is a provisional value from EPA-ECAO Regional Support.

BValue was calculated using the appropriate inhalation reference dose or inhalation slope factor with 20-m³ breathing rate and 70-kg adult body weight.

In these values were withdrawn from both IRIS and HEAST. However, Region III recommends using these values in deriving RBCs and they are presented in the Region III RBC table dated 1/31/95.

March 1996 3-28

^aCarcinogenic risk is expressed as a unitless probability of an individual developing cancer.

^bAge 15-18 (Grades 9-12) for the average case and age 6-19 (Grades 1-12, plus two repeat years) for the reasonable maximum case.

between projected intakes of COPCs over a specified time and toxicity values, primarily oral RfDs and inhalation RfCs. An HQ, which is the ratio between exposure to a chemical and that chemical's toxicity value, was calculated for each noncarcinogenic COPC and exposure pathway. Chemical-specific HQs were then summed for each COPC and each pathway of exposure to calculate the total HI.

The HI is not a statistical probability of a systemic effect occurring. If the exposure level exceeds the appropriate toxicity value (i.e., the HQ is greater than one), there may be cause for concern. The Superfund site remediation goal for noncarcinogens is a total HI of 1 for chemicals with similar toxic endpoints.

Table 3-13 summarizes the noncancer hazard estimates for each exposure scenario. The HIs for the residents and boarding students (except the future Old Town Galena resident) are 0 because none of the COPCs in soils are known to have systemic effects by the inhalation route and inhalation RfCs are not available. Inhalation of dust and vapors from the soils is the only applicable pathway of exposure for these scenarios. The HIs for all scenarios are below the Superfund site remediation goal of 1 for noncarcinogens, indicating that there is little cause for concern about noncarcinogenic effects.

Noncancer risk summary tables for each exposure scenario are provided in Appendix 4J of this volume. The tables detail the noncancer hazard estimates for each applicable chemical and exposure pathway and show the percent contribution of each chemical and pathway to the total estimated HI.

Effects of Exposure to Lead

The maximum detected concentration of lead at the CTDSA is 77 mg/kg in the surface soil. Lead is not a COPC in groundwater. The maximum soil concentration is well below the 400 mg/kg recommended screening level for lead in residential soil (USEPA, 1994d), which was derived using the IEUBK lead model (USEPA,

1994b). Since the soil concentrations are well below the soil screening level, lead was not evaluated further.

Major Factors Driving Estimated Risks

Tables 3-14 and 3-15 present a risk characterization summary for carcinogenic risk estimates and noncarcinogenic hazard estimates, respectively. For each scenario the tables specify the exposure pathways that were quantified, the estimated risks for each case, the chemicals and pathways that are major contributors to the estimated risks, and the primary uncertainties associated with the estimates. At the CTDSA, there are no chemicals or pathways that contribute a cancer risk greater than 1 in one million or an HI greater than 1.

3.3.5 Uncertainty Assessment

The risk characterization results are not fully probabilistic estimates of risk but rather conditional estimates of risk that should be interpreted in light of the considerable number of assumptions required to quantify exposure, intake, and dose-response. Uncertainties associated with identification of COPCs, the exposure assessment, and the toxicity assessment all contribute to the level of confidence that can be placed in the risk characterization results.

In general, risk assessment uncertainty was addressed in the BRA by the following:

- 1. Incorporating both average and reasonable maximum values for input parameters, whenever possible, to provide a range of results rather than a single value;
- 2. Erring on the side of conservatism when defining the reasonable maximum case; and
- 3. Identifying and discussing the major sources of uncertainty and their effect on the risk estimates so that the results can be properly interpreted.

Table 3-13
Summary of Noncarcinogenic Hazard Indices^a by Exposure Scenario for the Control Tower Drum Storage Area, South

Table 3-16 summarizes the primary sources of uncertainty specific to this assessment and the likely impact on risk estimates.

3.3.6 Conclusions and Recommendations

The CTDSA does not pose an unacceptable health risk to current on-base residents, Old and New Town Galena residents, workers who spend a majority of the workday outside in the immediate vicinity of the CTDSA, or to future boarding school students. The site also does not pose unacceptable health risk to future Old Town Galena residents who may use the shallow groundwater for drinking water if and when contaminants in the groundwater at the site migrate to Old Town Galena.

On the basis of the results of the human health assessment, there is no need to propose remedial action at the CTDSA.

3.4 Ecological Risk Assessment Results

3.4.1 Site Ecology

Figure 3-3 shows the location and features of the CTDSA, including topography. The CTDSA consists primarily of industrial development, and thus ecological features are limited. The BLM uses the eastern portion of the site to park aircraft and refueling trucks. Vehicle traffic may also occur at other parts of the site, and small aircraft may taxi through this area as well. A portion of the site is slated to be paved for the expansion of the tarmac near the control tower (Figure 3-3). This action will further reduce habitat quality. The CTDSA is mostly grass and gravel with a few stands of willow, alder, and spruce at the north edge of the site. Besides common birds such as robins and sparrows that are found throughout the Galena Airport, wildlife has not been noted on the site. Use of this area by fauna is marginal, and is likely to be limited to the common birds previously mentioned. Owing to the lack of accessible habitat and human activities, receptor exposure to surface soil at the CTDSA was not evaluated. Groundwater located beneath the site that might migrate to the shoreline of the Yukon River was evaluated for aquatic and semiaquatic receptors (i.e., pike, invertebrates, and spotted sandpiper).

3.4.2 Chemicals of Potential Ecological Concern

The results of the RI suggest the presence of limited areas of elevated VOC and TPH concentrations. These data are consistent with minor surface soil contamination from small leaks and spills. Aircraft and vehicle traffic are likely to be sources of hydrocarbons at this site. As stated above, ecological receptor exposure to soil was not considered because of lack of habitat. Thus, there were no COPECs for soil. A groundwater model was developed to estimate potential migration of chemicals to the Yukon River (see Appendix 4C). Groundwater COPECs for the CTDSA are presented in Table 3-17 and include organochlorine pesticides and VOCs. Section 3.2.2 in Volume 1 details the methods of COPEC identification. This table includes all chemicals in the groundwater with positive results greater than background and blank concentrations that were not eliminated as essential nutrients.

3.4.3 Exposure Assessment

Figure 3-4 shows the conceptual model for potential receptors and exposure pathways at the CTDSA. The area provides little ecological habitat because of industrial development, human activity, and lack of vegetation. Transportation of contaminants to the Yukon River via groundwater was the only exposure pathway evaluated. Ecological receptors evaluated in this pathway were the northern pike in the Yukon River and invertebrates and the spotted sandpiper at the shoreline. This pathway is the only potential ecologically significant exposure route for this site. The assessment and measurement endpoints are shown in Table 3-18.

3.4.4 Effects Assessment

EQs were calculated for the assessment endpoint species at the CTDSA. The results of this evaluation are presented in Table 3-19. Supporting spreadsheets are presented in Appendix 4K.

Table 3-16
Summary of the Major Uncertainties Associated with the Risk Estimates

Source of Uncertainty	Impact on Risk Characterization
Chemicals of Potential Concern	
Samples representing site media	Could result in an overestimate or underestimate of risks if the samples do not adequately represent media at the site. However, the number and location of samples collected at the CTDSA were sufficient to identify the area of contamination in soils and groundwater and assess the magnitude and extent of contamination. Surface soils, however, were defined as encompassing the top two feet of soil. Since exposures are generally limited to the top several inches, inclusion of the top two feet probably overestimates risk for surface soil pathways.
Analytical methods used to test samples	If the analytical methods used do not apply to some chemicals that are present at the site, risks could be underestimated. Since a full suite of analytical methods was selected to test for chemicals known or suspected to be present at the site, the potential for underestimation is reduced.
Presence of pesticides	Pesticides detected at the CTDSA were evaluated in the same fashion as all other COPCs. However, the pesticides result from widespread application for insect control and estimated risks from exposure to pesticides are not attributable to the CTDSA.
Contamination of blanks	Sporadic presence of chemicals in blanks samples was accounted for in blanks comparison. Blanks data do not indicate extensive field or laboratory contaminants.
Tentatively identified compounds	Tentatively identified compounds were not reported or assessed. Most such chemicals are not known to be highly toxic.
Diesel Range Organics and Gasoline Range Organics	DRO and GRO were not evaluated in the risk assessment as groups of chemicals. The assessment addresses individual chemicals only that were speciated by chemical analysis, which includes many constituent compounds of DRO and GRO. However, some constituent compounds were not on the target analyte list. The majority of the risk associated with exposure to DRO and GRO is probably accounted for in an assessment of individual chemicals.
Detection Limit Adequacy	The minimum detection limit for a few analytes in groundwater that were eliminated as COPC (because they were not detected) exceeds the USEPA Region III tap water RBCs. These include several PNAs, PCBs, SVOCs, and VOCs. The same is not true for analytes in the soil (when compared to Region III residential soil ingestion RBCs). If these analytes are in fact present and were contributed to the groundwater by site-related activities, the estimated risks for this site may be underestimated. However, since 1993 and later sampling events reported uncensored data (where an ND is reported only if there is no instrument response), the impact on the risk estimates is minimized.

Table 3-16 (Continued)

Source of Uncertainty	Impact on Risk Characterization
Exposure Assessment	
Use of current measured concentrations to represent current and future concentrations in the exposure media	Because concentrations of chemicals in the soils and groundwater at the CTDSA may decrease over time as the chemicals migrate and/or degrade, risks estimates for the current scenarios do not necessarily represent risks that will occur in the future.
Inclusion of groundwater pathways	Most Old Town Galena residents have their drinking water trucked in from the New Town area; however, there are at least seven wells still in use in the Old Town area (USAF, 1995b). Use of the shallow groundwater for tap water, therefore, cannot be ruled out. Risks associated with use of the shallow groundwater do not apply to residents who use other sources of water for domestic purposes.
Groundwater modeling	Results of groundwater modeling are indicative of worst-case concentrations that might reach Old Town Galena and the Yukon River. Impacts are likely overestimated for the groundwater pathways.
Estimation of plant uptake of COPCs from groundwater	Models to estimate plant uptake of chemicals are extremely simplified and could lead to an over- or underestimate of COPC concentrations in fruits and vegetables. Since the shallow groundwater is assumed to provide 100% of the plants' water requirements, either through irrigation or subirrigation, the concentrations in fruits and vegetables are probably overestimated.
Access to site	Access to the CTDSA is open. On-base residents and Galena residents are not restricted from walking on the site. Exposure of a roaming resident was not quantified (see discussion in Section 3 of Volume 1). If a resident spends a significant amount of time in the CTDSA area, estimated risks for that resident may be underestimated.
Tarmac expansion	The planned tarmac expansion will reduce the size of the area that is available for direct human exposures. Therefore, risks that were quantified assuming exposure to the entire area are probably overestimated.
Exposure parameter estimation	The standard assumptions regarding body weight, period exposed, life expectancy, and population characteristics may not be representative of any actual exposure situation. Some assumptions may underestimate risks, but most probably overestimate risk. In some cases, nonstandard assumptions were used for site-specific reasons, such as the reasonable maximum exposure duration of 70 years for Galena residents. The use of a 14-year exposure duration for the boarding school student overstates the likely duration of residence for most students.

Table 3-16 (Continued)

Source of Uncertainty	Impact on Risk Characterization
Toxicity Assessment	
Absence of toxicity values for some chemicals detected at the site	Lack of toxicity values may result in underestimation of risk; however, most chemicals that lack toxicity values are not very toxic or carcinogenic. Therefore, the degree of underestimation is probably low.
Use of unverified toxicity values for some chemicals	Could result in an overestimate of risk. However, chemicals with unverified toxicity values do not contribute significantly to estimated risks at the CTDSA.
Bases for derivation of toxicity values	Some common sources of uncertainty in toxicity values include 1) use of information obtained from dose-response studies conducted in laboratory animals to predict effects that are likely to occur in humans; 2) use of dose-response information from effects observed at high doses to predict adverse health effects that may occur at the low levels to which humans are likely to be exposed in the environment; 3) use of information obtained from short-term exposure studies to predict health effects in humans exposed on a long-term basis; 4) use of toxicity values that have been developed for one route of exposure and employing it under a different exposure route; and 5) use of information gathered in studies using homogeneous animal populations (inbred strains) or health human populations (occupational exposures) to predict the effects that are likely to occur in the general human population.
Absence of dermal toxicity values	Unadjusted oral toxicity values were used to evaluate dermal exposures. Since most oral values are based on administered dose and dermal exposure is quantified as an absorbed dose, risks from dermal exposure might be underestimated. PNAs were not evaluated for dermal exposures per USEPA guidance (see discussion in Section 3 of Volume 1). PNAs are associated with neoplasia in a variety of mammalian systems. The inability to quantify risks from dermal exposure to PNAs results in an underestimation of risks for the dermal pathway for PNAs.
Possible synergistic or antagonistic effects of exposure to multiple chemicals	Unknown impact on risk estimates. Chemical- and pathway-specific risk and hazard quotients are summed to account for possible additive effects.
Risk Characterization	
Applicability of cancer risk estimation methodology to subchronic exposure durations	The estimated intake for cancer risk estimation is averaged over a 70-year period. Exposure to higher concentrations of potential carcinogens for a short duration of time probably does not have the same effect as exposure to lower concentrations over a long duration.

3.4.5 Ecological Risk Characterization

Table 3-20 lists the EQ values greater than 1 for the aquatic and semiaquatic species. This table also provides the order of magnitude of the EQ results. Table 3-21 lists the percent contribution to the spotted sandpiper EQ from water and invertebrates.

3.4.6 Uncertainty Assessment

Uncertainty occurs in almost every step of the ERA process. As stated previously, uncertainty is often addressed by making intentionally biased (health conservative) assumptions so that impacts will not be underestimated. Individual assumptions are therefore conservative, but because of compounded bias the calculated EQs are biased higher than any individual assumption. Table 3-9 in Volume 1, Section 3 lists the uncertainties associated with the ERA. Table 3-22 lists the uncertainties associated with the ERA conducted for the CTDSA.

3.4.7 Conclusions and Recommendations

Aquatic (surface water → pike)

This exposure pathway considered groundwater beneath the CTDSA that potentially could migrate to the Yukon River, where exposure to the northern pike potentially could occur. None of the COPECs evaluated in this assessment showed an EQ above 1 for the northern pike. AWQC were used as the measurement endpoints when they existed. AWQC are highly conservative, since they are designed to protect most aquatic species.

Semiaquatic (surface water → aquatic invertebrate → spotted sandpiper)

This exposure pathway used modeled concentrations of contaminants in groundwater discharging to the surface at the Yukon River shoreline. No dilution or volatility factors were applied to the discharged concentrations. An EQ greater than 1 for 4,4'-DDE was noted for the spotted sandpiper and is shown in Table 3-20. This EQ indicates possible risk to the spotted sandpiper. There were no COPECs noted to have EQs above 1 for the aquatic invertebrate.

Spotted Sandpiper

The EQ in the spotted sandpiper for DDE was 6.03. EQs did not exceed 1 for the aquatic invertebrates or the northern pike. AWQC were used as the TBs and are highly conservative, since AWOC are designed to be protective of most aquatic life. NOAEL values obtained for the heron were used to assess impacts to the spotted sandpiper. DDT and its metabolites (DDE and DDD) are organochlorine pesticides that are recalcitrant and lipophilic compounds that can enter the food chain easily and progressively biomagnify to organisms at the top of the food chain such as fish-eating birds. Because of the extensive past use of DDT worldwide, and the persistence of the compounds, these materials are virtually ubiquitous and are continually being transformed and redistributed in the environment. A steady-state BCF of 12,000 for rainbow trout was applied to estimate the concentration in the aquatic invertebrate as the food for the spotted sandpiper. This value is based on ingestion of fish lower on the food chain and exposure to the surrounding media (i.e., water and sediment) (ATDSR, 1994). Table 3-21 indicates that 99% of the EQ contribution was from invertebrate ingestion and only ingestion of water. was from Organochlorine pesticides such as DDT were used extensively at the Galena Airport for insect The CTDSA does not represent a control. unique source for DDT and its metabolites.

In summary, constituents were evaluated for their aquatic toxicity, and chemical and physical effects in an aquatic system (i.e., the Yukon River) if their calculated EQ exceeded 1 for the assessment endpoint species. For the northern pike and aquatic invertebrate, it was determined that there was not significant potential for risk from the CTDSA groundwater discharge. AWQC were used as the measurement endpoints when they existed. AWQC are highly conservative, since they are designed to protect most aquatic life. Organochlorine insecticides could possibly affect the spotted sandpiper population adversely. Organochlorine insecticides such as DDT historically were used over

4,4'-DDE	6.03	0.9	99

Table 3-22 Uncertainties of ERA at the CTDSA

Parameter	Assumption	Uncertainty
Pathway: Surface Wa		1
Groundwater migra- tion	Groundwater beneath the POL migrates and is discharged to the Yukon River where exposure to the pike occurs.	Concentrations were modeled from the POL to the shoreline with no co-mingling or interferences. The magnitude of the uncertainty would be low, bias neutral.
	Groundwater modeling accurately estimated the concentration of COPECs in the Yukon River.	Due to restricted dilution (5 ft. from shore- line) actual concentrations that pike are ex- posed to are probably over-estimated. Con- centrations may be higher or lower. Magni- tude of uncertainty would be low-high, bias high.
Assessment endpoint species - Pike	Pike are present in the Yukon River near Galena all year.	Pike are present in the general area, but may not be near Galena all year. The ERA assumption is conservative, uncertainty would be low, bias high.
Pathway: Surface water	er → Invertebrates → Spotted Sandpig	per
Groundwater migra- tion	Groundwater modeling accurately estimated the concentration along the mudflats/shoreline	No dilution, volatility factors or attenuation was applied to these concentrations. Actual exposure concentrations are likely much lower than predicted. The magnitude of uncertainty would be low, bias high.
Exposure concentration and time	Invertebrates and sandpiper are exposed to the estimated concentrations at the mudflats during entire time species are on site.	Invertebrates may remain in a small geographic area and could be exposed to discharging groundwater continually; however, the spotted sandpiper is mobile and this assumption is highly conservative. The magnitude of uncertainty is low, bias high.
-	The spotted sandpiper's water intake is 100% from the discharging groundwater.	The spotted sandpiper travels along the shore- lines searching for food. To assume that 100% of water intake is from discharging groundwater is highly conservative. The magnitude of uncertainty is low, bias high.
Bioavailability of COPECs	All COPECs were assumed to be 100% bioavailable.	Bioavailability changes as physical conditions such as pH or % carbon changes. This assumption is conservative. The magnitude would be low-high, bias high.
Bioconcentration factors	Bioconcentration factors (BCF) were applied to estimated invertebrate tissue concentrations of COPECs.	BCFs can vary depending on conditions of the study that determined the BCF. Applied to this ERA, they may over or underestimate tissue concentrations. Magnitude of uncertainty is low-high, bias neutral.

March 1996 3-46

the entire Airport for insect control, and the CTDSA does not represent a unique area of contamination. AWQC were used as the TBs and are highly conservative, since they are

designed to be protective of most aquatic life. NOAEL values in birds were used to assess impacts to the spotted sandpiper.

Section 4 COMBINED IMPACTS

The Southeast Runway Fuel Spill site and the CTDSA are located about 1600 ft apart in the central area of the airport. The POL Tank Farm and the West Unit (evaluated in Volume 1) are located adjacent to each other on the west side of the installation. The FPTA (also evaluated in Volume 1) is less than two miles away on the east side of the installation. Additive impacts of all five sites are considered in Section 4.1 for the human health assessment and in Section 4.2 for the ecological assessment.

4.1 Human Health Assessment

For the human health assessment, combined impacts of individual exposure scenarios and individual sites are evaluated.

4.1.1 Exposure Scenario Combinations

Combinations of exposure pathways make up a defined exposure scenario. It is sometimes possible that one individual can be exposed to site-related contaminants by the pathways represented in more than one exposure scenario. Exposure scenario combinations that are possible and were addressed include the following:

- 1. Child and adult Galena resident (to represent an individual who is born in Galena and continues to live there through adulthood);
- On-base resident and on-base worker (to represent an individual who lives and works on base); and
- 3. Construction workers at individual sites (to represent construction workers who work at more than one site during different time periods).

Child and Adult Galena Resident

If the child scenario is added to the adult scenario for Galena residents, the average case represents an individual born in Galena who resides there for 31 years (6 + 25 years) and the reasonable maximum case represents a 76 year exposure duration (6 + 70 years). Combined child plus adult scenario cancer risk estimates for current Old Town Galena residents are as follows:

	Average	Reasonable <u>Maximum</u>
FPTA	7E-10	2E-09
POL Tank Farm	6E-08	2E-07
West Unit	1E-08	3E-08
Southeast Runway	8E-06	4E-05
CTDSA	7E-12	2E-11

These risk estimates are well below levels of concern, except for the Southeast Runway Fuel Spill site estimates. Although the combined risk estimates at this site exceed 1 in one million, they are not substantially higher than those already reported for child and adult residents individually and do not alter conclusions based on the individual results. Combined noncancer HIs are well below levels of concern at all sites. Combined risk estimates for New Town Galena residents are lower than those for Old Town Galena.

Evaluation of the Southeast Runway Fuel Spill site and the CTDSA also involved quantifying risks for future Old Town Galena residents, assuming migration of contaminants in the groundwater to locations in Old Town Galena and use of the shallow groundwater as tap water. Combined child plus adult scenario cancer risk

estimates for future Old Town Galena residents are as follows:

	Average	Reasonable <u>Maximum</u>
Southeast Runway	5E-05	2E-04
CTDSA	3E-07	1E-06

These risk estimates are not substantially higher (within same order of magnitude) than those already reported for child and adult residents individually and do not alter conclusions based on the individual results.

On-Base Resident and On-Base Worker—It is likely that many on-base residents also work on base. Adding the risks estimated for the on-base resident to that estimated for the on-base worker will overstate the risks for the resident who works on base because it is assumed that the resident is exposed for 24 hours/day to contaminants in the air medium at the location of the residences. However, because the estimated risks for the long-term on-base resident are either 0 or several orders of magnitude lower than the estimated risks for the long-term on-base worker at all five sites, combined risk estimates are the same as the estimated risks for the worker.

Construction Workers—Combined cancer risk estimates for a construction worker who works at each of the five sites during different time periods total 7E-05 for the average case (which assumes a three-month construction project at each site) and 1E-04 for the reasonable maximum case (which assumes a six-month construction project at each site). Estimated cancer risks for the construction worker at the FPTA, the West Unit, the Southeast Runway Fuel Spill site, and the CTDSA are at least an order of magnitude lower than those estimated at the POL Tank Farm; therefore, the combined risks are

essentially the same as the POL Tank Farm estimates. Combined noncancer HIs do not exceed 1.

4.1.2 Site Combinations

Media that might receive contributions of contaminants from the different sites at the same location include ambient air, groundwater, and surface water in the Yukon River.

Ambient Air—Each of the five sites contributes volatile and dust emissions to the air that were modeled to residential and boarding school student receptor locations. Risk estimates for the individual sites considered only the contribution of that site. Estimated combined cancer risks from inhaling contaminants in the ambient air from all five sites are as follows:

	Average	Reasonable <u>Maximum</u>
Short-term On-Base		
Resident (adult)	5E-08	1E-07
Long-term On-Base		
Resident (adult)	2E-07	7E-07
Old Town Galena		
Resident (adult)	6E-08	2E-07
New Town Galena		
Resident (adult)	4E-09	2E-08
Boarding School		
Student (student)	4E-07	1E-06

Combined cancer risks for the air pathway remain lower than 1 in one million for all residential scenarios and was equal to 1 in one million in the reasonable maximum case for the boarding school student scenario. However, this risk estimate is based almost entirely (98%) on exposure at the POL Tank Farm. Combined HIs for the air pathway for all scenarios remain lower than 1. Air pathway estimates for the worker scenarios were not combined; presumably the ambient air directly above a site is more

March 1996 4-2

heavily affected by emissions to the air from that site than it is by emissions from a more distant site.

Groundwater—Several of the groundwater contaminant plumes from source areas within the West Unit have commingled, and groundwater modeling considered the contribution of each source together (e.g., groundwater at the Waste Accumulation Area and Power Plant UST No. 49). However, it is unlikely that groundwater plumes from the FPTA, the POL Tank Farm, the West Unit, the Southeast Runway Fuel Spill site, and the CTDSA will commingle to any great extent before discharging to the Yukon River. Commingling of groundwater plumes from the West Unit and POL Tank Farm might occur but it is unlikely to significantly increase groundwater concentrations at any one location. Even if the plumes do commingle, the implications to identified receptors are minimal. There are no existing wells in areas downgradient of the West Unit and POL Tank Farm, nor are there likely to be wells installed in the future that draw from the shallow groundwater. Therefore, the combined impact of the five sites on groundwater quality is not evaluated.

Surface Water—Groundwater that flows under each of the sites discharges to the Yukon River. It is possible that discharges that occur at an upstream site will commingle with the discharges from other sites. The modeling that was performed takes additive impacts into account. Concentrations that are predicted in the river include the contribution of the individual site plus the contribution of upstream sites or source areas. For example, the estimated concentrations in the river attributed to the CTDSA actually include the contributions of other sites that discharge upstream of the CTDSA, such as the Southeast Runway Fuel Spill site and the FPTA. Consequently, additive impacts on the

surface water in the river and uptake by fish have already been addressed.

4.2 Ecological Assessment

Combined impacts for ecological receptors may occur in two ways: through exposures to a receptor by more than one pathway (e.g., ingestion of soils and ingestion of food items) and/or through exposures of a receptor to contaminants at more than one IRP site.

4.2.1 Combined Pathways

Exposures to trophic exposure pathways are evaluated on a site-specific basis for the FPTA, POL Tank Farm, and the West Unit in Sections 4.4, 5.4, and 6.4, respectively (evaluated in Volume 1). Results of these assessments are summarized here and exposure from multiple sites is also detailed.

FPTA-For the FPTA, EQs were derived that considered multiple pathways for the kestrel (ingestion of soil and savannah sparrows), red fox (ingestion of soil and meadow voles), meadow vole (ingestion of soil and plants), savannah sparrow (ingestion of soil and invertebrates), and spotted sandpiper (ingestion of water and invertebrates). The relative contribution of each pathway for each species is shown in Tables 4-25 and 4-26 (in Volume 1). One primary pathway of exposure was considered for terrestrial plants (exposure to soils), terrestrial and aquatic invertebrates (exposure to soils and surface waters, respectively), and the northern pike (exposure to surface water). Thus, combining pathways was applicable for these species.

Risk to plants, terrestrial invertebrates, red fox, and kestrel were determined to be minimal. Through evaluation of the toxicity data and physical properties of the contaminants with EQs above 1 in the context of the FPTA, it was determined that only dioxin and fluorene

have potential for risk to the meadow vole. Dioxin had an EQ in the possible risk range (1 < EQ < 10), and fluorene had an EQ in the probable risk range (EQ > 10). The potential risk from dioxin was primarily from soil ingestion (93.9%); the potential risk from fluorene was primarily from ingestion of food (plants, 85.9%). After consideration of toxic and physical properties for contaminants with EQs above 1 for the savannah sparrow, it was determined that only DDT, its breakdown products, and dioxin showed potential for risk. DDT and its breakdown products were in the probable risk range, and dioxin was in the possible risk range. Potential risk from all of these chemicals was primarily from consumption of food (97.7% contribution to total EQ from invertebrates).

For the aquatic and semiaquatic pathways, potential risks to the pike were minimal. Aquatic invertebrates were evaluated with AWQC for the protection of most aquatic life, and EQs in the possible risk range were derived for dieldrin, heptachlor epoxide, and lead. An EQ in the probable risk range was derived for DDT. For the spotted sandpiper, an EQ was derived that estimated the potential for risk from exposure to contaminants from the ingestion of groundwater discharged at the Yukon River mudflats and food ingestion pathways. percent contribution of each of these pathways to this EQ is presented in Table 4-25 of Volume 1. DDT exhibited probable risk to the sandpiper with 99% contribution from the food ingestion pathway. Lead exhibited possible risk with 72.3% contribution from the water ingestion pathway.

It should be noted that pesticides (DDT, dieldrin, and heptachlor) were historically broadcast throughout the Airport for pest control, and therefore, the FPTA does not represent an isolated area of high concentrations.

POL Tank Farm—Combined pathways were used to assess risk for the spotted sandpiper from potential POL Tank Farm groundwater discharge to surface waters of the Yukon River. The relative contributions of potential risks due to water ingestion and aquatic invertebrate ingestion are presented in Table 5-22 of Volume 1. Single pathways were used to evaluate impacts to aquatic invertebrates and the northern pike because only risk from exposure to groundwater discharge was considered important.

Toxic, chemical, and physical effects in the context of the Yukon River for those chemicals with EQs greater than 1 were evaluated for all assessment endpoints. For the northern pike, no significant potential for risk from POL Tank Farm groundwater discharge was determined. Chemicals that were considered to pose potential risk to aquatic invertebrates and the spotted sandpiper were DDT, 2-methylnaphthalene, lead, and thallium. DDT, 2-methylnaphthalene, and thallium exhibited EQs in the probable risk range, whereas the EQ for lead was in the possible risk range. For the spotted sandpiper, these EQs combined effects from ingestion of surface waters and aquatic invertebrates. Table 5-22 of Volume 1 shows that potential risks were primarily due to ingestion of invertebrates, except for thallium and lead where ingestion of surface water was the primary pathway.

Organochlorine pesticides historically were used over the entire Airport for insect control, and the POL Tank Farm does not represent a unique area of contamination. Dilution and adsorption to sediments can attenuate the assessment endpoint species' exposure to lead and thallium. On the basis of the transient nature of the mudflats or shoreline as an ecosystem, and the dilution of the constituents as they enter surface water, the population impacts of groundwater from the POL Tank Farm at the mudflats is minimal.

West Unit—Combined pathways for the West Unit were used to assess risk for the Waste Accumulation Area, Million Gallon Hill, Building 1845, and JP-4 Fillstands groundwater discharge impacts to the spotted sandpiper at the Yukon River mudflats. The contributions to potential risks due to water ingestion and aquatic invertebrate ingestion were combined in the EQ evaluation (Table 6-26 in Volume 1). Single pathways were considered for assessment of impacts to aquatic invertebrates and the northern pike because only risk from exposure to groundwater discharge was considered important for evaluation.

No chemicals were found to pose significant risk to northern pike in the Yukon River. After consideration of toxic and physical properties for contaminants with EQs above 1 (Table 6-25 of Volume 1), only dieldrin for aquatic invertebrates and DDT for both invertebrates and the spotted sandpiper were shown to have significant potential for posing risk in the Yukon River mudflats from groundwater originating from the Waste Accumulation Area. The EQ for dieldrin was in the possible risk category and the EQs for DDT were in the probable risk The combined impacts of water category. ingestion and invertebrate ingestion were assessed for the spotted sandpiper. Table 6-30 of Volume 1 shows that 99% of the potential risk was from ingestion of invertebrates. assessment shows potential for risk to these pesticides. However, the pesticides originating from the Waste Accumulation Area do not represent high concentrations relative to the Galena area in general because such chemicals were historically applied for pest control.

Contaminants shown to have significant potential for risk to aquatic invertebrates and the spotted sandpiper at Million Gallon Hill are DDT, DDE, and DDD. The assessment of potential risk for these chemicals for the sand-

piper included evaluation of ingestion of surface water and ingestion of aquatic invertebrates. Table 6-30 of Volume 1 shows that 99% of the potential risk was from ingestion of invertebrates. Consideration of toxic and physical properties for other Million Gallon Hill contaminants with EQs above 1 (Table 6-25 of Volume 1) indicates that these chemicals are not likely to pose significant risk to assessment endpoints at the Yukon River mudflats or shoreline.

Organochlorine pesticides from Bldg. 1845 and the JP-4 Fillstands groundwater potentially pose significant risk to aquatic invertebrates and the spotted sandpiper at the Yukon River mudflats. For the aquatic invertebrates, DDT, DDE, DDD, aldrin, dieldrin, endrin aldehyde, and heptachlor epoxide are pesticides with EQs above 1 for groundwater discharge from Bldg. 1845, and for the JP-4 Fillstands, DDT, DDD, aldrin, and endrin aldehyde are groundwater discharge chemicals with EQs above 1. For the spotted sandpiper, DDD, DDE, and DDT, are pesticides with EQs above 1 for groundwater discharge from Bldg. 1845, and for the JP-4 Fillstands, DDT, DDD, are groundwater discharge chemicals with EQs above 1. The assessment of potential risk for these chemicals for the sandpiper included evaluation of ingestion of surface water and ingestion of aquatic invertebrates. Table 6-30 of Volume 1 shows that 99% of the potential risk form pesticides was from ingestion of inverte-Consideration of toxic and physical properties for other Million Gallon Hill contaminants with EQs above 1 (Table 6-25 of Volume 1) indicates that these chemicals are not likely to pose significant risk to assessment endpoints at the Yukon River mudflats.

The only areas of the West Unit with potential for terrestrial impacts (population survivorship and productivity) were the Waste Accumulation Area and Million Gallon Hill. In

each of these areas, EQs were derived that considered multiple pathways for the kestrel (ingestion of soil, water, and robins), fox (ingestion of soil, water, and meadow voles), meadow vole (ingestion of soil, water, and plants), and robin (ingestion of soil, water, and invertebrates). The relative contribution of each pathway is given in Table 6-28 of Volume 1. One primary pathway of exposure was considered for terrestrial plants (exposure to soils) and terrestrial invertebrates (exposure to soils).

In both of these terrestrial areas of the West Unit, EQs for DDD, DDE, and DDT were above 1 for the robin. DDT had an EQ of 1.08 in the kestrel from the waste accumulation area, but this was the only risk determined for the kestrel, an upper trophic level receptor. Also in the Waste Accumulation Area, an EQ of 10.4 was calculated for gamma-BHC (Lindane) in the terrestrial invertebrate.

Southeast Runway Fuel Spill Site—Similar to those at the FPTA, EQs were derived that considered multiple pathways for the kestrel, red fox, meadow vole, robin, and spotted sandpiper. One pathway was considered for terrestrial plants, terrestrial and aquatic invertebrates, and the northern pike. Combining exposure pathways was applicable for all of these assessment endpoint species.

Risk to terrestrial invertebrates, red fox, and kestrel were determined to be minimal. Through evaluation of the toxicity data and physical properties of the contaminants with EQs above 1 in the context of the Southeast Runway Fuel Spill site, it was determined that PNAs have potential for risk to the meadow vole and the robin. Additionally, bis(2-ethylhexyl)phthalate may have impacts on the robin and lead may have potential for risk to terrestrial plants. All of the EQ levels for the terrestrial receptors were below 10, with the

exception of benzo(b)fluoranthene, which had an EQ in the probable range (EQ > 10) in the robin. For the meadow vole, direct ingestion of soil accounted for 50 to 78% of the exposure to PNAs, whereas robin exposure occurred through ingestion of the invertebrate (78%). Exposure of the robin to bis(2-ethylhexyl)phthalate was almost completely due to ingestion of terrestrial invertebrates (99%).

For the aquatic and semiaquatic pathways, potential risks to the pike and spotted sandpiper were minimal. Aquatic invertebrates and the northern pike were evaluated with AWQC as the TB, when available. AWQC are protective of aquatic life, and represent conservative TBs. EQs in the probable range were derived for 2-methylnaphthalene and fluorene in the aquatic invertebrate.

CTDSA—Combined pathways were used to assess the spotted sandpiper from groundwater discharge to surface waters of the Yukon River. Single impacts were used to evaluate impacts to aquatic invertebrates and the northern pike because only risk from exposure to groundwater discharge was considered important.

Chemicals with EQ values greater than 1 were reviewed for physical and chemical fate in the environment and toxicity in fish, freshwater aquatic invertebrates, and birds. review of toxicity and environmental fate, only 4,4'-DDE in the spotted sandpiper was shown to have potential for posing risk from groundwater originating from the CTDSA. The EQ for 4,4'-DDE was calculated to be in the possible category (i.e., 1 < EQ < 10). For the spotted sandpiper, an EQ was derived that estimated the potential for risk from exposure to contaminants from the ingestion of groundwater discharged to surface water at the shoreline and food (i.e., aquatic invertebrates). The aquatic invertebrate, as food for the spotted sandpiper, contributed 99% to the spotted sandpiper EQ. It should be noted that organochlorine insecticides (DDT, dieldrin, and heptachlor) were historically broadcast throughout the Galena Airport for insect control, and therefore, the CTDSA does not represent a source area of organochlorine insecticides.

4.2.2 Site Combinations

Sites with multiple source areas, such as the Galena Airport, have the potential for receptor exposure to more than one source area. Sections 4.4, 5.4, and 6.4.4 of Volume 1 estimate the potential for risk to assessment endpoints at the FPTA, POL Tank Farm, and the West Unit, respectively. The Southeast Runway Fuel Spill site and the CTDSA are presented in Sections 2.4 and 3.4. As described above, risk due to combinations of pathways has been considered in these estimates. This section estimates the potential for combined risk for receptor exposure to multiple sites.

For ecological receptors, the primary factors that affect exposure to multiple source areas are home range (mobility) and habitat availability. For most soil and sediment invertebrates and plants, multiple site exposure is precluded due to relative immobility. Species with relatively small home ranges are less likely to encounter multiple sites than are species with large home ranges. Moreover, even if home range size makes it possible for encounters of multiple sites, when the appropriate habitat is not available, it is not likely that multiple exposures will occur. The potential for multiple exposures was evaluated for the assessment endpoints at each IRP source area and is summarized below.

The FPTA is approximately 1.5 miles from the terrestrial ecological areas of concern at the West Unit (Waste Accumulation Area and Million Gallon Hill) and approximately 0.3

miles from the Southeast Runway Fuel Spill site. For terrestrial receptors, all species except the fox and the kestrel have home ranges that would preclude frequent encounters with both the West Unit sites and the FPTA; however, all of the mobile terrestrial receptors could frequent the FPTA and the Southeast Runway Fuel Spill site. The kestrel has a home range of approximately 499 acres (Appendix I, Volume 3), and the home range for the fox is approximately 1771 acres (Appendix I, Volume 3). Thus, strictly evaluating home range size indicates that these species easily would have access to any area of the Airport, assuming the center of their home range was within the Airport or near the Airport.

Available habitat for these two species is of better quality at the FPTA and Southeast Runway Fuel Spill site than at the West Unit. The FPTA is located in the large grasslands that surround the eastern runway areas, and there are areas of trees and shrubs along the perimeter dike to the north, east, and south. The dike area provides cover, nesting, and foraging sites for the fox. The dike provides cover and nesting sites for the kestrel. The grassland areas and edges of the wooded areas are good foraging areas for both species, although less so when the grasses are mowed frequently. The Southeast Runway Fuel Spill site is primarily vegetated with grass; however, alders and willows from along the slope of the dike providing habitat for perching birds which are commonly noted. These same habitat types are found at the Waste Accumulation Area, but Million Gallon Hill contains only wooded slopes and cleared, formerly wooded areas at the base of the hill that will presumably returned to wooded areas as taiga wetland. Thus, Million Gallon Hill offers little habitat for the kestrel because there are no open vegetated areas (e.g., grasslands) for foraging. Overall, the abundance of habitat is much less in both areas, the grassy areas of the

Waste Accumulation Area and Southeast Runway Fuel Spill site are mowed frequently reducing habitat value, and the degree of human disturbance is greater at the West Unit. Moreover, it is important to note for the fox that there is higher quality habitat outside of the Airport in undisturbed areas, thus further decreasing the likelihood of combined utilization of the source areas. For the kestrel, utilization of infrequently mowed grasslands in areas of human activity is common. However, the degree of human activity still can influence occurrence. Habitat available outside of the airport for the kestrel is not as abundant as for the fox; nevertheless, there are many open fields and woodland edge habitats available, further reducing the likelihood of combined use of the source areas.

At the FPTA and Southeast Runway Fuel Spill site, there were no EQ values indicating possible risk to the red fox or the kestrel. At the Waste Accumulation Area and Million Gallon Hill, there was no potential for risk to the red fox. The EO for the kestrel at the Waste Accumulation Area indicated possible risk. However, as explained above, the habitat at the Waste Accumulation Area is of less quality for the kestrel than at other available areas. Therefore, given the limited acreage of fox and kestrel habitat for West Unit source areas, the lack of habitat for the kestrel at Million Gallon Hill, the higher quality habitats at the FPTA and the Southeast Runway Fuel Spill site, the availability of habitat outside of the Airport, and the lack of EQs in the possible risk category, it is unlikely that there is a significant degree of combined risk due to multiple source area utilization for these assessment endpoints.

Combined utilization for terrestrial assessment endpoints of Million Gallon Hill and the Waste Accumulation Area is possible for the red fox, meadow vole, and robin because the

source areas are adjacent to each other, and the assessment endpoint home range sizes would allow contact with both source areas. As explained above, the kestrel is not likely to occur at Million Gallon Hill, precluding combined site impacts. No EQs were in the possible risk category for the red fox. Combined use of these sites for such a species that has a very large home range is likely to be minimal compared with the total habitat, thus minimizing the potential for combined use to cause potential risk.

For the meadow vole, EQs indicated possible risk for acenaphthene, benzo(a)anthracene, benzo(a)flouranthene, and benzo(g,h,i)perylene at Million Gallon Hill and the Southeast Runway Fuel Spill site. All of these chemicals also showed possible risk, except benzo(b)flouranthene, at the Waste Accumulation Area. As explained in Section 6.4 of Volume 1 and Section 2.4, risk to voles from PNAs at these sites in minimal due to the relatively low concentrations and the ability of vertebrates to readily metabolize these compounds. It is not likely that combined use of the Waste Accumulation Area, Million Gallon Hill, and the Southeast Runway Fuel Spill site would appreciably increase the potential for risk.

Combined site impacts to robins at the Waste Accumulation Area and Million Gallon Hill are possible for DDT, DDE, and DDD, which exhibited EQs above 1 for both sites. These chemicals were applied historically in the Galena area for pest control, and their presence at these two sites does not represent areas of elevated concentrations.

Multiple site exposure for aquatic and semiaquatic species is possible for those species utilizing multiple groundwater discharge areas. Groundwater discharge to surface waters of the Yukon River were modeled for the FPTA, POL Tank Farm, Waste Accumulation Area, Million

Gallon Hill, JP-4 Fillstands, Bldg.1845, CTDSA, and the Southeast Runway Fuel Spill site. Groundwater discharge for the FPTA is approximately 1.5 miles upstream from the discharge points for the remaining sites (Appendix C, Volume 3). Potential combined site impacts to Yukon River aquatic invertebrates at the discharge points are not likely. Also, it is not likely that potential migration of contaminants at the discharge points would significantly affect invertebrates downstream because of the low concentrations at the discharge points and subsequent dilution that would occur in route down stream.

There is a potential for combined impacts to aquatic invertebrates from groundwater discharging to the Yukon River mudflats/shoreline because the discharge points are either overlapping or adjacent to each other and comprise a high quality habitat (Appendix C, Volume 3). After consideration of toxic and physical properties and dilution effects of the river on chemicals with EQs greater than 1, it was determined that organochlorine pesticides were the primary chemicals that may pose risk to invertebrates of the mudflats (Section 6.4.7 of Volume 1). Additive concentrations of the discharging groundwater from various source areas were not evaluated in the groundwater model (Appendix C, Volume 3).

For the spotted sandpiper, utilization of the mudflats at the FPTA groundwater discharge point in conjunction with the discharge points of the POL Tank Farm and the West Unit areas is likely to be minimal because of the small home range size of the sandpiper (approximately 2.5 acres). Wading bird species with larger home ranges potentially could forage in both areas.

However, the abundance of other wetland and mudflat habitat in the area reduces probability of combined use of these areas.

There is a significant likelihood of use by the spotted sandpiper of the POL Tank Farm and source areas of the West Unit groundwater discharge points (mudflats) because these are either overlapping or adjacent to each other (Appendix C, Volume 3). After consideration of toxic and physical properties and dilution effects of the river on chemicals with EQs greater than 1, it was determined that organochlorine pesticides were the primary chemicals that may pose potential risk to wading birds such as sandpipers at the mudflats (Section 6.4.7 of Volume 1). Additive concentrations of the discharging groundwater to the same vicinity were not considered in the groundwater model (Appendix C, Volume 3). Thus, the effect on potential mudflat concentrations is uncertain. The abundance of locally available wetland habitat for foraging would reduce the magnitude of a potential combined use effect.

Combined impacts from all groundwater discharge sources is possible for the northern pike because individuals of this species can range over large areas. However, the only EQ indicating possible risk to pike was the EQ for manganese. It was determined that this metal is not likely to pose risk because of dilution effects and the fact that it is an essential metabolic element. Thus, given that all other EQs were below 1 and that the exposure concentrations modeled did not account for dilution, impacts to the northern pike from combined sources would be minimal (i.e., productivity and population survivorship would not be reduced).

Section 5 CONCLUSIONS AND RECOMMENDATIONS

5.1 Human Health Assessment

For each scenario addressed in this risk assessment, the carcinogenic risk was estimated on a chemical-by-chemical basis for each relevant pathway of exposure. The estimated cancer risk was summed for each chemical associated with a specific pathway to determine total risk by pathway. To determine the total exposure scenario risk, total risks for all pathways were summed. A similar procedure was performed to determine the total noncancer HI for each exposure scenario.

The USEPA Superfund site remediation goal set forth in the NCP designates a cancer risk of 10⁻⁴ (1 in 10,000) to 10⁻⁶ (1 in one million). This range is designed to be protective of human health and to provide flexibility for consideration of other factors in risk management decisions. In effect, risks that are less than 10⁻⁶ are generally considered negligible. Risks that are greater than 10⁻⁴ are usually considered sufficient justification for undertaking remedial action. Risks in the intermediate range between these two values can be considered acceptable on a case-by-case basis. The State of Alaska plans to use a cancer risk level of 10⁻⁵ (1 in 100,000) in making risk management decisions (USAF, 1996b).

The HQ is not a statistical probability of a noncarcinogenic effect occurring. If the exposure level exceeds the appropriate toxicity value (i.e., the HQ is greater than one), there may be cause for concern regarding the potential noncarcinogenic effects. The Superfund site remediation goal for noncarcinogens is a total HI of 1 for chemicals with similar toxic endpoints.

Table 5-1 summarizes the chemicals and exposure pathways that contribute an estimated

cancer risk greater than 1 in one million at the Southeast Runway Fuel Spill site and the The table specifies the applicable CTDSA. exposure scenario, the chemical-specific risk estimate, and the percent of the total risk, and provides summary comments to place the risk estimate in perspective. Of the numerous chemicals detected in environmental media at the two sites, only one chemical poses an estimated risk in excess of 1 in one million: beryllium in groundwater at the Southeast Runway Fuel Spill site. Estimated noncancer HIs are below 1, the Superfund site remediation goal for noncarcinogens, for all scenarios at both sites. An evaluation of combined impacts indicates that combining scenarios (e.g., child and adult) or adding individual site contributions to media at the same location does not substantially increase the estimated cancer risks or noncancer HIs.

Risks associated with residual petroleum at the sites are addressed by quantifying risks for individual chemicals that are components of the residual petroleum. The results of the risk assessment can be used to evaluate the need to remediate DRO and GRO, but are not intended to be used to establish alternate cleanup levels for DRO and GRO. Remediation issues related to DRO, GRO, and free product are to be addressed outside of the risk assessment.

It should be noted that the risk estimates presented address risks associated with the IRP sites under investigation and do not include risk associated with airport operations.

5.1.1 Southeast Runway Fuel Spill Site

Estimated incremental cancer risks for all scenarios except the current and future Old Town Galena residents are below 1 in one million, considered the *de minimis*, or level of

negligible risk. Estimated risks for the current Old Town Galena resident range from an average of 3 in one million to a reasonable maximum of 3 in 100,000 for an adult and from 4 in one million to 1 in 100,000 for a child. These risk estimates are within the Superfund risk range goal for carcinogens of 1 in 10,000 to 1 in one million. Estimated risks for the future Old Town Galena resident range from an average of 3 in 100,000 to a reasonable maximum of 2 in 10,000 for an adult and from 2 in 100,000 to 3 in 100,000 for a child. The reasonable maximum estimate for the adult exceeds the high end of the Superfund risk range goal.

In the current Old Town Galena resident scenario, ingestion of fruits and vegetables that take up beryllium from the shallow groundwater (either through irrigation or subirrigation) at the location of the gardens southwest of the site contributes the majority of the risks (97%) in all cases. Risks associated with exposure to all other chemicals are negligible. Likewise, in the future Old Town Galena resident scenario, 99% of the estimated risk in all cases is attributable to beryllium in groundwater. Ingestion of groundwater containing beryllium contributes most (85-95%) of the estimated risk; ingestion of fruits and vegetables that take up beryllium from the shallow groundwater (either through irrigation or subirrigation) at gardens in Old Town Galena contributes risks that exceed 1 in one million in some cases. Again, risks associated with exposure to all other chemicals are negligible.

Beryllium is a COPC in groundwater at the site because the background comparison concluded that average beryllium concentrations in groundwater at the site exceeded average beryllium concentrations in background groundwater. However, the level of confidence in this conclusion is rated as weak, based on the p-value of the comparison (0.0630). Moreover, the maximum detected concentration in ground-

water at the site (0.00394 mg/L) is lower than the calculated background UTL for beryllium in groundwater (0.005 mg/L). It is also lower than the USEPA MCL and MCLG for drinking water, which are both 0.004 mg/L. There is no reason to suspect that concentrations of beryllium in groundwater at this site might be elevated above background; although beryllium and beryllium alloys are sometimes used for various types of instrument springs, control parts, valves, and airplane carburetors and instruments, it is unlikely that these possible uses have resulted in elevated beryllium concentrations in groundwater at this site. Therefore, the estimated risks associated with exposure to beryllium at this site are probably no higher than risks from exposure to background concentrations of beryllium.

Moreover, the methodologies used to model the migration of beryllium in the ground-water from the Southeast Runway Fuel Spill site to Old Town Galena, and to estimate uptake by fruits and vegetables from groundwater, are conservative. The groundwater modeling accounted only for horizontal dispersion; vertical dispersion was ignored. The "source" was defined as 100 ft long with a concentration of 0.00394 mg/L (the maximum detected concentration). As a result, the modeled concentration at Old Town Galena (0.00113 mg/L) is higher than that detected at two of the four monitoring wells located at the site.

To calculate uptake by fruits and vegetables grown in gardens southwest of the site and in gardens in Old Town Galena, it was assumed that 100% of water required by the plants is supplied by shallow groundwater, either through irrigation or subirrigation. The depth of the groundwater fluctuates from very close to the surface to 15 to 20 ft below surface over the course of the year. It is unlikely that the roots of garden plants are in direct contact with the

groundwater (and thus are subirrigated) for a substantial portion of the growing season. It is more likely that precipitation and irrigation water from sources other than the shallow groundwater supply some or all of the water required.

Finally, most residents of Old Town Galena have drinking water trucked in from the city well in the New Town area, upgradient from Galena Airport. There are, however, at least seven private wells still in use in Old Town Galena (USAF, 1995b). Four of these wells, all less than 60 ft deep, were sampled in 1992 and 1993 as part of the RI. Results from beryllium were reported as ND; however, the detection limit was 0.002 mg/L.

If, as the evidence suggests, beryllium is not elevated above background in the groundwater at the Southeast Runway Fuel Spill site and it is removed as a COPC, the risks posed by the site are negligible for all human populations that might encounter site-related contaminants. Estimated risks associated with exposure to beryllium in the groundwater downgradient from the site are not significantly different from exposure to background concentrations of beryllium in the groundwater. On the basis of the results of the human health assessment, remedial action at the Southeast Runway Fuel Spill site is not warranted.

5.1.2 Control Tower Drum Storage Area, South

The estimated incremental cancer risks for all other scenarios at the CTDSA are below 1 in one million. Estimated noncancer HIs are well below 1 for all scenarios. On the basis of the results of the human health assessment, remedial action at the CTDSA is not warranted.

5.2 Ecological Assessment

Figures 5-1 and 5-2 summarize the

weight of evidence findings for local populations of the assessment endpoint species of this ERA. A weight-of-evidence analysis of potential effects on assessment endpoint species was conducted by reviewing the physical, chemical, ecological, and toxicological properties of the COPECs with EQs above 1. More specifically these properties included:

- Physical and chemical properties:
 - environmental persistence;
 - mobility;
 - degradation products; and
 - bioavailability to ecological receptors.
- Toxicological properties:
 - toxic effects to wildlife:
 - likelihood of metabolism;
 - metabolic products; and
 - excretion time.
- Ecosystem properties:
 - ecosystem type;
 - ecosystem use;
 - habitat quality; and
 - habitat use.

The first two segments of this ERA, problem formulation and analysis, provided a forum for all of these characteristics, but a final review was conducted considering the EQ evaluation. Once all of the input parameters were presented, a rating was given to the COPEC for the assessment endpoint species with EQ values above 1. This rating (high, medium, or low) provides the initial guidance for the decision-making process.

5.2.1 Southeast Runway Fuel Spill Site

No EQ values above 1 were obtained in this ERA for the invertebrate, red fox, or kestrel. Results of the risk evaluation for plants

were inconclusive, except for lead. Given the extreme conservatism associated with the terrestrial TB, the low EQ (1.02) for plants, the lack of impacts to the higher trophic levels, and the site lead level being within the general background agricultural levels, adverse effects of lead on terrestrial plants are not expected. Several PNAs were noted in the meadow vole with EQs greater than 1 (benzo(a)anthracene, benzo(a)pyrene, and benzo(g,h,i)perylene). Although all of these EQs were greater than 1, they were also less than 10, and are categorized as indicating possible risk; however, the potential for risk from PNAs in this EQ category is likely to be insignificant because current data indicate that vertebrates metabolize PNAs (Eisler, 1987), or the PNAs remain bound to soil particles in the gastrointestinal tract and therefore are not accumulated. Owing to the low EQ levels of these PNAs, low concentrations of PNAs when compared with those at other sites, lack of impact to the red fox, and physical and biological processes that limit the vertebrate toxicity, the effects of PNAs on the mammals in the terrestrial ecosystem are expected to be minimal.

As with the plant toxicity, little soil invertebrate toxicity information was found. Several TBs were identified; however, none of the EO results were above 1. Additionally, there were no EQs above 1 for the kestrel. For the robin, benzo(b)fluoranthene was the only contaminant evaluated with an EQ above 10 at 10.9. The only other chemical with an EQ above 1 for the robin was bis(2-ethylhexyl)phthalate, with an EQ of 1.09. As described above, the potential for risk from PNAs is likely to be insignificant because current data indicate that vertebrates metabolize PNAs (Eisler, 1987), or the PNAs remain bound to soil particles in the gastrointestinal tract and therefore are not accumulated (ATSDR, 1993). Information is limited on avian PNA toxicity. A "worst case" exposure is represented in this assessment by the TB. The applicability of this exposure route is dependent on several factors, including the form of the PNAs at the Southeast Runway Fuel Spill site and the use of the Southeast Runway Fuel Spill site as a breeding area for avian species. During the yearly flood, soil contaminants such as PNAs could be transported to the surface by the rising These contaminated surface waters waters. could potentially contact ecological receptors, especially as water accumulates at the dike. The Southeast Runway Fuel Spill site is vegetated with alders and other tall vegetation on the slope Perching birds are commonly of the dike. observed and nesting could occur in this vegetation. Because of the high quality of habitat along the dike, the propensity of birds, and possible transport and exposure mechanisms of contaminants to avian receptors, adverse impacts to avian receptors (especially eggs and young birds) could occur; however, the ability of vertebrate systems to metabolize PNAs and the strong adsorption of these compounds to soils limits the exposures and toxicities. Possible impacts on avian receptors at the Southeast Runway Fuel Spill site by PNAs are therefore given a medium rating.

The EO for bis(2-ethylhexyl)phthalate in the robin was calculated to be 1.09. Bis(2ethylhexyl)phthalate is bioconcentrated and the compound has been observed in invertebrates, fish and terrestrial organisms; however, accumulation of bis(2-ethylhexyl)phthalate is likely to be minimized by metabolism, and biomagnification in the food chain is not expected to occur. This has been confirmed by the detection of metabolites in animal tissues (ATSDR, 1991a). Because of the potential for metabolism of bis(2ethylhexyl)phthalate, lack of adverse impacts to the kestrel, and low EQ in the robin, the effects of bis(2-ethylhexyl)phthalate to the avian ecosystem at the Southeast Runway Fuel Spill site are expected to be minimal.

The aquatic and semiaquatic exposure pathway considered groundwater beneath the Southeast Runway Fuel Spill site that potentially could migrate to the Yukon River, where exposure to the northern pike, aquatic invertebrates, and spotted sandpiper potentially could occur. None of the COPECs evaluated in this assessment showed an EQ above 1 for the northern pike or spotted sandpiper. AWQC were used as the measurement endpoints for evaluation of the northern pike and aquatic invertebrates when they existed. AWQC are highly conservative since they are designed to protect aquatic life. 2-Methylnaphthalene and fluorene are the only compounds with EOs greater than 1 for the aquatic invertebrate. PNAs vary substantially in their toxicity to aquatic organisms. In general, toxicity and bioconcentration factors tend to increase as molecular weight increases (Eisler, 1987). Fluorene and 2-methylnaphthalene are both low molecular weight PNAs, with molecular weight values of 166.2 and 142.2 respectively (ATSDR, 1993), indicating low potential for bioconcentration or toxicity. PNA levels in fish and higher trophic levels are usually low because they are rapidly metabolized (Eisler, 1987). Because of the low potential for bioconcentration or toxicity from low molecular weight PNAs and the ability of higher trophic levels to metabolize PNAs, the adverse impacts from fluorene and 2methylnaphthalene are expected to be minimal.

The ERA indicates that impacts on perching birds, especially eggs and young, might occur due to the presence of PNAs in the surface soil. However, numerous birds have been noted at the site. Remediation of the groundwater is not required because of the lack of predicted impacts to ecological receptors at the shoreline.

5.2.2 Control Tower Drum Storage Area, South

This site evaluation considered ground-

water beneath the CTDSA that potentially could migrate to the Yukon River, where exposure to the northern pike, aquatic invertebrate, and spotted sandpiper potentially could occur. Terrestrial receptors were not considered owing to the lack of habitat at the CTDSA. None of the COPECs evaluated in this assessment showed an EQ above 1 for the northern pike or aquatic invertebrate. AWQC were used as the measurement endpoints for these assessment endpoint species when they existed. AWQC are highly conservative since they are designed to protect most aquatic life. No dilution or volatility factors were applied to the discharged concentrations. 4,4'-DDE had an EQ value greater than 1(6.03) for the spotted sandpiper, indicating possible risk. There were no other COPECs noted to have EQs above 1 for the spotted sandpiper. DDT and its metabolites (DDE and DDD) are organochlorine pesticides that are recalcitrant and lipophilic compounds that can enter the food chain easily and progressively biomagnify to organisms at the top of the food chain, such as fish-eating birds. Because of the extensive past use of DDT worldwide, and the persistence of the compounds, these chemicals are virtually ubiquitous and are continually being transformed and redistributed in the environment. A steady state BCF of 12,000 for rainbow trout was applied to estimate the concentration in the aquatic invertebrate as the food for the spotted sandpiper. This value is based on ingestion of fish lower on the food chain and exposure to the surrounding media (i.e., water and sediment) (ATDSR, 1994). An analysis of the intake model for the spotted sandpiper indicates that 99% of the EQ contribution was from invertebrate ingestion and only 1% was from ingestion of water. Organochlorine pesticides such as DDT were used extensively at the Galena Airport for insect control. The CTDSA does not represent a unique source for DDT and its metabolites.

On the basis of the results of the ecological assessment, remedial action at the CTDSA

is not warranted.

4A.1 INTRODUCTION

This appendix presents the results of the data evaluation performed to determine the chemicals of potential concern (COPCs) for use in the Galena Baseline Risk Assessment for the Southeast Runway Fuel Spill site (SE Runway) and the Control Tower Drum Storage Area, South (CTDSA).

COPCs were identified, in general, following the technical approaches described in Appendix A (Volume 2). COPCs were identified for both organic and inorganic analytes in soils and groundwater for the two sites that are the subject of this addendum. For this risk assessment, data were compiled from sampling efforts in 1994 and 1995. Soil data were divided into surface and subsurface classifications, using the same depth criteria described in Appendix A (Volume 2).

This appendix is divided into five sections. Section 4A.2 presents the COPCs identified for the CTDSA and the SE Runway. Section 4A.3 describes the technical approach used for this risk assessment, and Section 4A.4 gives results of the analyses performed. Lastly, references are in Section 4A.5. Additional tables with detailed results are given in Attachment 4A.1. The raw data used to determine COPCs is given in Attachment 4A.2. These attachments are included in the back of this appendix.

4A.2 SUMMARY

COPCs are chemicals that are positively identified as present at a site due to historical activities at the site. COPCs were determined using the statistical approach and procedures described in Appendix A (Volume 2) with minor modifications. The most significant change was that all 1994 and 1995 data were reported uncensored by the analytical laboratory for the CTDSA and SE Runway. The definition of "Occurrence" (as used to calculate "frequencies of occurrence" or "frequencies of detection") was redefined for 1994 as any result exceeding the upper tolerance limit for uncensored blank data; and for 1995 as any result not

flagged with a "B". The "B" flag indicated that the sample result was less than five times or ten times the maximum blank concentration for all blanks taken in 1995. The justification for this approach and other modifications are provided in this appendix.

Tables 4A-1 and 4A-2 give the possible COPCs for the CTDSA and SE Runway, respectively. The chemicals listed in these tables passed all the criteria to be retained as chemicals of potential concern per the USEPA definition (USEPA, 1989). They were subjected to additional screening before they were positively identified as COPCs for the human health evaluation or chemicals of potential ecological concern (COPECs).

4A.3 TECHNICAL APPROACH

The technical approach used to identify COPCs for this addendum uses the approach described in Appendix A (Volume 2) with minor modifications. The entire approach, including modifications, is described in this section.

COPCs were identified by a technical approach following the *Risk Assessment Guidance for Superfund Volume I Human Health Evaluation Manual* (USEPA, 1989). The evaluation to determine possible COPCs for the risk assessment is presented in Figure 3-2 in Volume 1 and includes the following steps as outlined in the USEPA guidance:

- Review raw data for representativeness;
- Review blank data;
- Compare site results to blank data;
- Perform comparisons between site and background concentrations for naturally occurring chemicals (i.e., inorganic chemicals).
- Calculate frequency of occurrence for site chemicals; and
- Calculate summary statistics for contaminants of potential concern.

March 1996 4A-4

Each of these steps are described in the following subsections.

4A.3.1 Review Raw Data for Representativeness

The first step in the COPC identification process is to review the available raw data for applicability. The USEPA guidance states that all available data should be used to determine COPCs if the data are of sufficient and comparable quality and representative of site conditions. According to USEPA guidance, this data review process must include an evaluation of the following areas:

- Data available from historical site investigations;
- Analytical methods;
- Quantitation limits; and
- Data qualifiers.

Each of these steps in the data review process is addressed below.

4A.3.1.1 Review of Data Available from the Site Investigation

A number of samples have been collected at Galena Airport during the two sampling efforts in 1994 and 1995. Many of these samples were collected in order to characterize sites for a risk assessment. USEPA guidance allows the compilation of data from different sampling events as long as several criteria are met. These criteria are:

- 1. if sampling methods were similar;
- 2. if analytical methods were similar;
- 3. if QA/QC procedures and criteria were similar;
- 2. if concentrations were similar (i.e., significant changes did not occur to the site between sampling events).

These criteria were met for all data where samples were collected in support of the risk assessment. However, this does not mean that data from all the samples collected were used in this risk assessment.

Data for each site were reviewed to ensure that only data appropriate for a risk assessment were used to identify COPCs. Often measurements were analyzed for the same analyte by more than one method. Measurements that were analyzed by a more exact or more sensitive method were used for the risk assessment. Table 4A-3 presents the preferred analytical methods chosen for analytes where data were available from multiple methods.

4A.3.1.2 Analytical Methods

For each of the two investigations, the approved sampling and analysis plans were implemented successfully and data were generated using the planned analytical methods. Thus, data for these methods were deemed acceptable for use in this determination of COPCs.

4A.3.1.3 Quantitation Limits

The third step in the data review, as specified in the USEPA guidance, involves the evaluation of "quantitation limits" for all of the chemicals assessed at the site. All laboratory analyses meet the sensitivity requirements of the QA plan.

Additionally, uncensored data were reported for many of the inorganic and organic analyses. The reporting of uncensored data improves the project's ability to determine if low-level contamination can be discerned from system noise. Uncensored data means that all results are reported, even those results below the quantitation limit that would normally be censored and reported as "ND". This includes the use of negative results when they were reported for inorganic constituents. For some of the organic and inorganic analytes, the data are automatically censored by the laboratory even when uncensored data are requested. This happens for those methods that use electronic filtering mechanisms to eliminate signals below

Table 4A-3 Multiple Analytical Methods Identified

Analyte	Media	Method Used (Method Not Used) for Baseline Risk Assessment
Site = Control Tower Drum	Storage Area	
1,2-Dichlorobenzene	Groundwater	SW8260 (SW8270)
1,3-Dichlorobenzene	Groundwater	SW8260 (SW8270)
1,4-Dichlorobenzene	Groundwater	SW8260 (SW8270)
Arsenic	Groundwater, Surface Soil	SW7421 (SW6010)
Lead	Groundwater, Surface Soil	SW7060 (SW6010)
Selenium	Surface Soil	SW7740 (SW6010)
Site = Southeast Runway		
Lead	Groundwater	SW7060 (SW6010)

a specified threshold (e.g., peak height, peak width, area reject). Proxy values were estimated for NDs using a uniform random number between 0 and the smaller of the minimum result and the MDL for each site and media, as described in Appendix A (Volume 2).

4A.3.1.4 Data Qualifiers or Codes

The fourth step in the data review process involves a review of data qualifiers or codes reported with the analytical results so that uncertainties can be identified and evaluated. All data that were validated during the QA/QC process were used to determine COPCs. This includes some data with qualifiers that indicate known identities, but uncertain concentrations. An additional step included during this phase of the risk assessment was a check if all results for an analyte in a specific matrix and site were KJ-flagged (a value that was not second column confirmed and was below the quantitation limit) or were not detected. If all results were KJ-flagged or were not detected, then the analyte was treated as if all results were not detected and the analyte was automatically eliminated as a COPC for that site and matrix.

4A.3.2 Review of Blank Data

Blank results can be used to evaluate the "noise" in the analytical system (field and laboratory components) to verify whether site concentrations were in fact greater than the analytical noise. For this phase of the program, upper tolerance limits (UTLs) established in the first phase of the program (Appendix A, Volume 2) for the 1994 sampling year were used for 1994 data: a site result greater than the blank UTL was considered a positive occurrence for that chemical. Blank results from the 1995 sampling year were used to set B-flags (B-flags identify those results that are due to analytical noise and do not indicate the presence of a chemical.). Since there were not enough blank results to accurately calculate UTLs for the 1995 data, the B-flags were used to identify analytical "noise". For 1995 data, a site result that was not B-flagged was considered a positive occurrence for that chemical. For more information about how B-flags were set, see the 1995 RI Report (USAF, 1995).

4A.3.3 Frequencies of Occurrence for Site Data

The third step in the COPC determination process was to compare the site data to the blank data to determine the potential for false-positive measurements because of laboratory or field contamination and to determine if target analytes occur frequently enough to be retained as a COPC. Frequencies of occurrence were calculated for each analyte, where a positive occurrence was any result from 1994 greater than the UTL for the blanks or any result from 1995 that was not B-flagged. Similar to the first phase of this risk assessment, analytes with positive occurrences less than five percent were considered separately based on detected results and applicable screening levels. Analytes with a frequency of occurrence greater than or equal to 5% for any site were retained as a COPC in the risk assessment. Inorganic analytes were further evaluated by comparing site results to background concentrations, as discussed in the next section.

4A.3.4 <u>Comparison of Inorganic Site Concentrations to Naturally Occurring Background Levels</u>

The fourth step in the COPC determination process was to compare site results to background levels for naturally occurring chemicals. A statistical "means comparison" was performed between site and background concentrations to determine if there was any evidence of metals contamination on the site. In addition, an "individuals comparison" was performed to determine the potential for a hot spot. A summary of the background data that were used for these comparisons and an overview of these two types of tests used can be found in the Appendix A (Volume 2).

4A.3.5 Calculate Summary Statistics for COPCs

The next step in the data analysis was to calculate summary statistics for those analytes determined to be possible COPCs (i.e., analytes retained through all the previously described steps). Measurement values for non-detect results were estimated by substituting

uniform random numbers between 0 and the smaller of the minimum result and the sample specific method detection limit for each site and for each matrix, analytical method, and analyte. Average site concentrations and the 95% upper confidence limit for the average were calculated for COPCs for each site. The upper confidence limit was calculated by strictly following USEPA guidance (USEPA, 1992c). Before calculating the 95% upper confidence limit, each set of results (by matrix, analytical method, and analyte) was tested with the Shapiro-Wilk test to determine whether the data set had a normal distribution, a log-normally distribution, or had neither distribution. Using the appropriate distribution, the 95% upper confidence limit was then calculated. For data that had neither distribution, a normal upper confidence limit was calculated. These summary statistics were used by the risk assessors to perform further screening of the COPCs as well as conduct risk assessments.

4A.4 RESULTS

This section presents the results of the data analyses performed to determine COPCs for the risk-based screen and the risk assessment. Results are presented for each of the following steps in the COPC determination process:

- Review blank data using previously determined upper tolerance limits for blanks in 1994 and using B-flags associated with 1995 data;
- Compare site results to appropriate blank information, and calculate a combined frequency of occurrence for site chemicals from both 1994 and 1995 sampling events;
- Perform comparisons between site and background concentrations for naturally occurring chemicals (i.e., inorganic chemicals) for all of the data.

Additionally, the summary statistics calculated for contaminants of potential concern are presented.

4A.4.1 Review of Blank Data

The Quality Assurance/Quality Control Summary reports for the respective years of sampling contain a discussion of the validity of the blank results and associated site results. Blank UTLs for 1994 that were previously calculated in the first phase of this risk assessment and the maximum B-flagged value for 1995 sampling data were used to represent the upper limit of measurements expected for the blank population (i.e., the upper limit of "noise" due to sampling or analysis activities). For 1994 sampling data, site results greater than the blank UTLs were concluded to indicate potential site contamination, and for 1995 sampling data, site results without a B-flag were concluded to indicate potential site contamination. Results, taken in 1994, less than the blank UTLs and results, taken in 1995, that have B-flags were concluded to be potentially analytical system noise and not indicative of site contamination.

4A.4.2 Frequencies of Occurrence for Site Data

The frequency of occurrence was calculated for each analyte, site, and matrix by determining the percent of results that exceeded the blank UTL for 1994 and were not B-flagged for 1995. These results are given in Attachment 4A, Table 1-1, for groundwater, and Table 2-1, for soils, for each site, respectively. In addition to the blank UTLs and the calculated frequencies of occurrence, these tables show the number of samples collected from each site and the range of site results (minimum and maximum). The tables also show whether or not the chemical was retained as a possible COPC and a footnote describing the reason a chemical was or was not retained as a possible COPC.

4A.4.3 <u>Comparison of Inorganic Site Concentrations to Naturally Occurring Background Levels</u>

As discussed in Section 4A.3.4, the fourth step in the COPC determination process was to compare concentrations of naturally occurring chemicals to background concentrations to determine if there is any evidence of metals contamination on the site due to

past practices. Section 4A.4.3.1 below, discusses tables of the background data that were used for these comparisons and Section 4A.4.3.2 gives the results of these comparisons.

4A.4.3.1 Characterization of Background Data

In the first phase of the risk assessment report (Volumes 1-3), Tables A-4 and A-5 in Appendix A give summary statistics (e.g., minimum, maximum, mean) for the water (groundwater) and soils (surface and subsurface) background data, respectively, for each metal. In addition to summary statistics, these tables show the number of samples collected and give information on the UTLs that were calculated for background. More information about background metals data can be found in Section 2 of the RI Report (USAF, 1995).

4A.4.3.2 Means and Individuals Comparisons of Inorganic Site Concentrations to Background

Tables with the results of the means and individuals comparisons for waters and soils are given in Attachments 4A.1, Table 1-2, for groundwater, and Table 2-2, for soils. These tables show the p-values (i.e., the probability that the two means come from the same parent population) for the tests of central tendency, the conclusion (S = statistically significant at the 0.20 alpha level), the power of the test, and the type of statistical test performed (i.e., Student's t-Test or Wilcoxon test). The power of the test represents the probability of detecting a difference of 40% between the background mean and the site mean at the 80% confidence level. These criteria are recommended in the *Guidance for Data Useability in Risk Assessment* (EPA 1992a). They also show the background UTLs and the number of site results exceeding the UTLs (i.e., the results of the individual comparisons). The last two columns of these tables indicate whether or not it was listed as a possible COPC and a reason for this conclusion.

4A.4.4 <u>Calculate Summary Statistics for COPCs</u>

The next step in the data analysis was to calculate summary statistics for those analytes retained as possible COPCs throughout this process. Organic analytes that had a frequency of occurrence that was greater than or equal to 5% for a given site were initially identified as COPCs. Inorganic analytes that had a frequency of occurrence greater than or equal to 5% and had average concentrations that were significantly greater than background were also initially identified as COPCs. Any analyte that had a frequency of occurrence less than 5% was evaluated to determine if it should remain a possible COPC.

The following summary statistics were calculated for all analytes that were determined to be COPCs: minimum, maximum, mean, and 95% upper confidence limit for the mean. For censored data, proxy concentrations were estimated for values reported as ND by substituting a random uniform number between zero and the smaller of the minimum result or the MDL. This approach was used so that the proxy concentration was not biased high with respect to the sensitivity of the analytical measurement methods.

Table 1-3 and Table 2-3 in Attachment 4A.1 give summary statistics for possible COPCs for waters (groundwater) and soils (surface and subsurface soils), respectively.

4A.4.5 Raw Data

Raw data tables are provided in Attachment 4A.2 for groundwater, surface soil, and subsurface soil. These tables provide the data source, the lab sample id, the analytical method, the estimated concentration (measured value or proxy value if ND), and the MDL for that measurement.

Definition of Footnotes

- No measureable results on site.
- Average metal concentration on site significantly greater than average background metal concentration (alpha = 0.20). ъ э.
- Average metal concentration on site not significantly greater than average background metal concentration (alpha = 0.20). ပ
 - Frequency of occurrence >= 5%. ė,
 - Frequency of occurrence < 5%. ė.
- No UTL for blanks was calculated and frequency of measureable results >= 5%.
 - No UTL for blanks was calculated and frequency of measureable results < 5%.
- Results are either not detected or KJ-flagged. ÷ 6 ÷

N = 15

ND = Not detected.

NC = Not calculated. UCL cannot be calculated with only one site result.

NOTE: A mean associated with Log Normal data was calculated using a scale bias correction factor.

a. Random uniform numbers, between zero and the lesser of the minimum result and the detection limit, substituted for non-detected values.

b. One-sided 95% upper confidence limit for the mean.

Definition of Footnotes

- Average metal concentration on site significantly greater than average background metal concentration (alpha = 0.20). a. No measureable results on site. b. Average matel
- Average metal concentration on site not significantly greater than average background metal concentration (alpha = 0.20). ပ
 - Frequency of occurrence >= 5%. o;
- Frequency of occurrence < 5%.
- No UTL for blanks was calculated and frequency of measureable results >= 5%.
- No UTL for blanks was calculated and frequency of measureable results < 5%. ÷
 - Results are either not detected or KJ-flagged.

APPENDIX 4B

RISK-BASED SCREENING

Note: Methodology for conducting risk-based screening is described in Section 3 of Volume 1.

APPENDIX 4B LIST OF TABLES

		Page
4B-1	Screening Results for Southeast Runway—Surface Soil	4B-1
4B-2	Screening Results for Southeast Runway—Subsurface Soil	4B-3
4B-3	Screening Results for Southeast Runway—Groundwater	4B-5
4B-4	Screening Results for Control Tower—Surface Soil	4B-7
4B-5	Screening Results for Control Tower—Groundwater	4B-10
4B-6	Detection Limit Screening for Surface Soil for the Southeast Runway Fuel Spill Site	4B-12
4B-7	Detection Limit Screening for Subsurface Soil for the Southeast Runway Fuel Spill Site	4B-15
4B-8	Detection Limit Screening for Groundwater for the Southeast Runway Fuel Spill Site	4B-18
4B-9	Detection Limit Screening for Surface Soil for the Control Tower Drum Storage Area	4B-21
4B-10	Detection Limit Screening for Groundwater for the Control Tower Drum Storage Area	4B-24

Table 4B-1 Screening Results for Southeast Runway—Surface Soil

Chemical of Potential Concern	CAS number	Classification	Screening Result
Benzo(a)pyrene	50-32-8	PNA	Yes
Dibenz(a,h)anthracene	53-70-3	PNA	Yes
Benzo(b)fluoranthene	205-99-2	PNA	Yes
Benzo(a)anthracene	56-55-3	PNA	Yes
Indeno(1,2,3-cd)pyrene	193-39-5	PNA	Yes
Lead	7439-92-1	Metal	NV ^a
Phenanthrene	85-01-8	PNA	NV
Benzo(g,h,i)perylene	191-24-2	PNA	NV
2-Methylnaphthalene	91-57-6	PNA	NV

NV = No toxicity values are available for this analyte. A screening level was not calculated for this analyte.

PNA = Polynuclear aromatic hydrocarbon.

^a Risk from exposure to lead is evaluated using the USEPA IEUBK model.

4E.1 INTRODUCTION

Uptake of contaminated shallow groundwater by locally grown vegetables may contribute to concentrations of certain chemicals in edible portions of plants. The concentration of chemicals in plants subirrigated with contaminated water depends on the concentration of the chemical in the shallow groundwater, the water solubility and lipophilicity of the chemical, the plant type, and other factors. Volatile chemicals as well as non-volatile chemicals were evaluated for this pathway at the Southeast Runway Fuel Spill site and Control Tower Drum Storage Area, South (CTDSA). Because the vegetable gardens may take in water through tap roots which access the shallow groundwater, these constituents are not volatilized to the atmosphere via agitation and volatilization that can occur with above ground irrigation.

Currently, Galena residents grow vegetables in gardens southwest of the Southeast Runway Fuel Spill site. Therefore, maximum concentrations of groundwater chemicals of potential concern (COPCs) were taken from wells MW-03 and MW-04 located near the Southeast Runway Fuel Spill site and the gardens. These concentrations were used in the fruit and vegetable uptake model for the current Old Town Galena resident (see Table 4E-1). For the future Old Town Galena resident, modeled groundwater concentrations in Old Town Galena were used in the fruit and vegetable uptake model. See Appendix C (Volume 3) for a discussion of the groundwater modeling and see Appendix 4C of this volume for the groundwater modeling results for the two sites that are the subject of this addendum.

Direct deposition of chemicals from dust and particulates in the air onto the soil and edible parts of fruit and vegetables may also occur. However, the relative contribution to contaminant concentrations in plants by this pathway is expected to be minor in comparison to the contribution by subirrigation with groundwater. The extent of surface contamination at the Southeast Runway Fuel Spill site and the CTDSA is limited to small areas. Moreover, any dust generated at the site is likely to settle to the ground fairly near

the site because of the generally large particle size of dust generated from soil. Also, washing of fruit and vegetables prior to consumption generally removes a large percentage of the deposited dirt and dust. Overall, dust contribution to plant uptake is likely to be insignificant compared to uptake from groundwater, given the extremely conservative methodology used to calculate uptake from groundwater.

4E.2 UPTAKE BY FRUIT AND VEGETABLES SUBIRRIGATED WITH SHALLOW GROUNDWATER

The chemical concentration in fruit and vegetables with roots that take up contaminants directly from the shallow groundwater was derived as follows (USEPA, 1986):

$$C_{ts} = TSCF \times C_{w}$$

where:

 C_{ts} = Concentration in transpiration stream ($\mu g/L$);

TSCF = Transpiration stream concentration factor (unitless); and

 C_w = Concentration in water (groundwater) (μ g/L).

and

$$C_f = (C_{ts} \times WC_p)/1000$$

where:

C_f = Concentration in fruit and vegetables (mg/kg);

 WC_p = Water content of plant (%); and

1/1000 = Conversion factor (1 mg/1000 μ g × 1 L/kg).

The transpiration stream concentration factor (TSCF) was calculated as follows (USEPA, 1986):

TSCF = $0.784 \exp - [\log K_{ow} - 1.78]^2/(2.44)]$

Tables 4E-1 through 4E-3 list the calculated TSCF values for chemicals of potential concern in the shallow groundwater.

For water content of plant (WC_p) a mid-range value from the range presented in USEPA (1986) for fruits and green vegetables (0.84) was used to derive an average concentration in fruit and vegetables and the highest value in the range (0.94) was used to derive a reasonable maximum concentration in fruit and vegetables.

Tables 4E-1 through 4E-3 contains the spreadsheet calculations for uptake by fruit and vegetables directly from the shallow groundwater.

4F.1 METHODOLOGY

Use of contaminated water in residences for bathing/showering may contribute concentrations of volatile chemicals in the indoor air. The method used to estimate concentrations in air while showering is based on results of shower volatilization experiments (Andelman, et al., 1986). The experiments involved pumping a tracer chemical (aqueous trichloroethene) solution through an experimental shower chamber and measuring resulting concentrations of the tracer in the air. The experiments revealed the following: 1) The trichloroethene concentration increased in approximately a linear fashion over time; 2) The volatilization was higher at higher water temperatures; and 3) The volatilization rate increased when the height of the shower water drop path increased. The percent volatilization during the experiment ranged from 43 to 79 percent.

A kinetic-mass-balance relationship that predicts concentrations of volatile chemicals in air as a function of time was developed by Andelman (Andelman et al, 1986). The basic mass balance equation is:

$$V_A(dC_A/dt) = (R) - (F_AC_A)$$

where:

 $V_A = Chamber volume (m³);$

 $dC_A/dt = Rate of change in concentration in air (g/m³/min);$

R = Mass of chemicals volatilized per unit time (g/min);

 F_A = Air flow rate (m³/min);

 C_A = Concentration of a particular volatile compound in air (g/m^3) .

and where:

$$R = k(C_w - C_A/H)$$

where:

C_w = Concentration of a particular volatile compound in water (g/m³);

H = Henry's Law Constant (dimensionless); and

k = Volatilization transfer coefficient (m 3 /min).

Since k equals F_w (water flow rate) at complete volatilization and F_A (the air flow rate) is much greater than F_w , k/H can be neglected. Combining these equations and treating k/H as insignificant, the equation reduces to:

$$V_A(dC_A/dt) = (kC_w) - (F_AC_A)$$

Integrating, we get:

$$Ln(1-F_AC_A/kC_w) = -(F_A/V_A)t.$$

This equation is used to predict concentrations as a function of time in the shower. The maximum value for k, the volatilization transfer coefficient, is assumed to be equal to F_w (the water flow rate) at 100% volatilization (Andelman, et al., 1986). In the absence of experimental data, $k=F_w$ will give the worst-case concentration in the shower at different times.

However, Andelman's work with experimental showers showed that the percent of trichloroethene in water that volatilizes is less than 100%, varying from 43 to 79% (Andelman, at al., 1986). The k value (at steady state = $C_A F_A/C_w$) drops significantly from 100% to between 5% and 15% when the percent volatilization drops from 100% to the range of 43 to 79 percent. For trichloroethene, therefore, it is conservative to assume a k value that is 50% of the maximum value. Since $k=F_w$ is the maximum value for k, corresponding to 100% theoretical volatilization for trichloroethene, 50% of the water flow rate is a justifiable estimate for k.

Experimental data on percent volatilization in showers was not available for all the chemicals of potential concern (COPCs) for this assessment. By considering the relative volatility of a specific chemical compared to the volatility of trichloroethene, k values can be estimated for the COPCs, as

follows:

$$k = 0.5 F_w X \frac{VP_c}{VP_{TCE}}$$

where:

VP_c = Vapor pressure of chemical (mm at 48°C); and

 VP_{TCE} = Vapor pressure of trichloroethene (which is 200 mm at 48°C).

This approach is applicable to chemicals with vapor pressures lower than the vapor pressure of trichloroethene, as well as chemicals with vapor pressures higher than the vapor pressure of trichloroethene but less than or equal to 400 mm Hg. For chemicals with vapor pressures higher than 400 mm Hg, use of this equation provides an estimate for the k value which is higher than the maximum value $(k=F_w)$. For these chemicals, $k=F_w$ was conservatively assumed.

Many factors affect the volatilization of a compound from water to air. These include thermodynamic or physical properties of a chemical, aqueous solubility, vapor pressure, Henry's law constant and diffusivity.

Andelman's work with TCE showed that the percent volatilized varied between 67 to 79%. A relative volatility based on the vapor pressure of less volatile compounds was used to estimate k and then estimate volatilization from water. Henry's law constant was not used for the following reasons:

- 1. Henry's law constants are difficult to obtain for temperatures other than 25°C. Vapor pressures on the other hand can be easily obtained.
- 2. Henry's law constant usage in a shower model situation is not appropriate. In a shower, water is sprayed from a shower head at higher temperatures than ambient temperatures. The water usually breaks down into smaller droplets (with a large surface area). Henry's law constant does not account for this situation. Henry's law constants are determined for quiescent water layers. The spraying action in a shower would make more compounds volatilize than in a quiescent state. Vapor pressure is probably more appropriate to use in this situation.

3. By linking the relative volatility to that of TCE, for which data are available, a more realistic estimate for volatilization is obtained. In addition, TCE is very sparingly soluble in water. Therefore, by linking compounds to TCE by use of a relative volatility function, estimates for volatilization are more conservative.

Other assumptions include:

- 1. Water flow rate = 20 L/min [based on findings of a U.S. Department of Housing and Urban Development survey that the mean and maximum value for water flow rate in showers is between 10 L/min and 30 L/min (Andelman et al, 1989)];
- 2. Air exchange rate 1 per hour (a conservative value suggested by Andelman et al., 1989);
- 3. Dimensions of the shower stall = $5.5 \times 3 \times 8$ ft (volume = 3.736 m^3); and
- 4. Shower duration = 7 minutes for the average shower duration and 15 minutes for the reasonable maximum (USEPA, 1989).

Tables 4F-1 and 4F-2 present the shower vapor concentrations for both the average and reasonable maximum scenario for the future Galena residents at the Southeast Runway and Control Tower sites.

-- No value

No shower concentrations were derived for beryllium because it does not readily volatilize.

These are groundwater results from wells MW-03 and MW-04 that are close to the gardens and Southeast Runway site. These values are maximum concentrations of groundwater chemicals of potential concern detected in these wells. q

See Appendix 4C for groundwater modeling results.
See Appendix 4D for air emissions estimating and dispersion modeling in ambient air results.
See appendix 4F for air inside shower stall calculations, methodology, and modeling results.
See Appendix 4E for fruit and vegetables uptake methodology and modeling results.

APPENDIX 4I

HUMAN HEALTH TOXICITY PROFILES

Note: Toxicity Profiles for all other human health COPCs are in Appendix G (Volume 3)

APPENDIX I TABLE OF CONTENTS

									•		I	age
4I.1	Antimony	 		 		I-1						

4I.1 Antimony

Antimony toxicity data in humans is available from both accidental poisonings and occupational exposures. Acute illnesses occurred in 70 people who drank lemonade containing 0.013% antimony. The lemonade contained approximately 36 mg antimony/300 mL lemonade (approximately 0.5 mg/kg for a 70 kg adult). Acute signs of toxicity included stomach pain, colic, nausea, and vomiting. Recovery was complete in three hours to several days (Dunn, 1928; Monier-Williams, 1934).

Occupational exposure has resulted in a variety of toxic effects. Respiratory disorders include pneumonitis, alterations in pulmonary functions, chronic bronchitis, chronic emphysema, inactive tuberculosis, pleural adhesions and irritation. Increases in blood pressure and altered EKG readings, gastrointestinal disorders, dermatitis, and ocular conjunctivitis also have been seen (ATSDR, 1990). Myocardial effects are among the best characterized human health effects associated with antimony. In one study, the no observed effect level (NOEL) for myocardial damage from inhalation exposure was suggested to be approximately 0.5 mg/m³ (Brieger, 1954). However, the database regarding heart damage is not sufficient to estimate the myocardial NOEL with any confidence. A higher incidence of spontaneous abortion was reported in workers exposed to antimony (Belyaeva, 1967). A high rate of premature deliveries among workers in an antimony smelting and processing plant was also reported (Aiello, 1955).

In a chronic study in rats, a group of 50 males and 50 females received 5 ppm potassium antimony tartrate in water (Schroeder et al., 1970). The growth rates of treated rats were not affected, but males survived 106 fewer days than did controls at median lifespans, and female rats survived 107 fewer days. Nonfasting blood glucose levels were decreased in treated males, and cholesterol levels were altered in both sexes. A decrease in mean heart weight for males was noted. No increase in tumors occurred. The 5 ppm antimony exposure was expressed as 0.35 mg/kg/day by the authors. Because only one level of antimony was administered, a NOEL was not established.

The oral RfD for antimony in IRIS is 4E-04 mg/kg/day. This is based on the chronic study in rats noted above. The uncertainty factor used to derive the RfD for antimony is 1000. This adjusts for interspecies conversion, sensitive individuals, and the use of a LOAEL in place of the NOEL. IRIS confidence in the supporting study was low. Only one species and one dose level were used, and no NOEL was determined. Gross pathology and histopathology were not described well. IRIS confidence in the database was also low. There is no inhalation RfC for antimony. HEAST lists a subchronic oral RfD of 4.00E-04 mg/kg/day. No carcinogenicity data exists in IRIS or HEAST for antimony. The Threshold Limit Value for antimony is 0.5 mg/m³ (8-hour time weighted average) (ACGIH, 1993-1994).

											Page	3
4K-1	Site Areas	 	 	 							4K-2	2

4K.1 INTRODUCTION

Constants used in the exposure assessment for the ERA are listed below. Assessment endpoint species contaminant intake is detailed in Section 3.2.3 of Volume 1. Spreadsheets showing the calculations are shown in Appendix 4M. The size of the sites are shown in Table 4K-1. The areas were also used in the intake estimation. Areas are based on the extent of soil contamination.

4K.1.1 Meadow Vole

The values used to calculate meadow vole exposure are:

- Body weight: 0.039 kilograms (EPA, 1993);
- Water intake: 0.0053 Liters per day (calculated using methodology in Section 3.2.3);
- Food ingestion rate: 0.0049 kilograms dry matter per day (calculated using methodology in Section 3.2.3);
- Percent of food from contaminated source: 100%;
- Fraction of food in diet: 0.97;
- Fraction of soil in diet: 0.024 (Beyer et al., 1993); and
- Home range: 0.034 acres (EPA, 1993).

4K.1.2 <u>Spotted Sandpiper</u>

The values used to calculate spotted sandpiper intake are:

- Body Weight: 0.047 kilograms (EPA, 1993);
- Water intake: 0.67 Liters per day (calculated using methodology in Section 3.2.3);

Table 4K-1 Site Areas

Site or Source Area	Acres
Southeast Runway Fuel Spill	6.32
CTDSA	3.78

- Food ingestion rate for seabirds: 0.00744 kilograms dry matter per day (calculated using methodology in Section 3.2.3);
- Fraction of food in diet: 0.82;
- Fraction of soil in diet: 0.18 (value for western sandpiper, Beyer et al, 1994);
- Home range: 2.5 acres (CDFG, 1990); and
- Time on site: 5 months (May September, Robbins, 1983).

4KI.1.3 Red_Fox

The values used to calculate red fox intake are:

- Body weight: 5.25 kg (male, EPA, 1993);
- Water intake: 0.44 Liters/day (calculated using methodology in Section 3.2.3);
- Food ingestion rate: 0.268 kilograms dry matter/day (calculated using methodology in Section 3.2.3);
- Percent of food from contaminated source: 100%;
- Fraction of food in diet: 0.97;
- Fraction of soil in diet: 0.028 (Beyer et al., 1993); and
- Home range: 1771 acres (EPA, 1993).

4K.1.4 Robin

The values used to calculate robin intake are:

Body weight: 0.077 kilograms (Dunning, 1993);

- Water intake: 0.0105 Liters/day (calculated using methodology in Section 3.2.3);
- Food ingestion rate: 0.01597 kilograms dry matter/day (calculated using methodology in Section 3.2.3);]
- Percent of food from contaminated source: 100%;
- Fraction of food in diet: 0.896;
- Fraction of soil in diet: 0.104 (Woodcock, Beyer et al., 1993); and
- Home range: 2.00 acres (foraging home range fledglings, EPA, 1993).

4K.1.5 American Kestrel

The values used to calculate American kestrel intake are:

- Body weight: 0.120 kilograms (female, Dunning, 1993);
- Water intake: 0.014 Liters/day (calculated using methodology in Section 3.2.3);
- Food ingestion rate: 0.01096 kilograms dry matter/day (calculated using methodology in Section 3.2.3);
- Percent of food from contaminated source: 100%;
- Fraction of food in diet: 0.90;
- Fraction of soil in diet: 0.10; and
- Home range: 499 acres (EPA,1993).; and
- Time on site: 6 months.

4K.1.6 Northern Pike

Northern Pike intake was not assessed, therefore no intake parameters are

listed.

4K.1.7 <u>Invertebrates (Aquatic and Terrestrial)</u>

Invertebrate intake was not assessed, therefore no intake parameters are listed.

to be important. Evidence exists for the uptake of benzene by cress and barley plants from soil; however, because benzene exists primarily in the vapor phase, root uptake is not expected to be a such as styrene, cumene, and cyclohexane. Benzene is also used for the manufacturing of some types of rubber, lubricants, dyes, detergents, drugs, and pesticides. The high volatility and water of 24, benzene is not expected to bioconcentrate to any great extent in aquatic organisms. On the basis of estimated and measured BCFs, biomagnification in aquatic food chains does not appear solubility of benzene are the physical properties with the greatest influence on environmental transport and partitioning. Benzene released to soil surfaces partitions to the atmosphere through runoff and to groundwater as a result of leaching. Benzene is considered highly mobile. On the basis of a reported log K_w of 2.13 and an estimated BCF sources, which include volcanoes and forest fires, account for a small amount of benzene in the environment. Benzene is also a natural part of crude oil. It is used widely and is ranked in the top 20 in production volume for chemicals produced in the United States. Most of the benzene is produced from petroleum sources. Various industries use benzene to make other chemicals, major source of vegetative contamination. Air to leaf is expected to be the major pathway of vegetative contamination. Benzene is biodegradable in surface water and soil under aerobic Benzene, also known as benzol, evaporates into air quickly and dissolves easily in water. Benzene found in the environment is from both natural processes and human activities. conditions (1).

Bioconcentration:

- General BCF (estimated) = 24
 - Barley plant BCF = 17 Cress plant BCF = 10
- Goldfish BCF = 4.24 (1)

Environmental Fate:

- $Log K_{oc} = 1.8-1.9$
- Henry's Law Constant = 5.5×10^{-3} atm m³/mol at 20°C
 - Water Solubility = 1,780 mg/l at 25°C
- Vapor Pressure at 25°C = 95.2 mmHg Henry's Law Constant at 25° C = 5.5×10^{3} atm-m³/moL

Ecological Toxicity Profile for Benzo(a)anthracene

Organism	Dose	Exposure Route	Exposure Period	Effect	Endpoint	Reference
			Benzo(a)anthracene	hracene		
Rat	180 mg/kg	Oral	Acute	Oncogenic transformation		1
Mouse	18 mg/kg	Dermal	Acute	Skin tumors		2
Mouse	2 mg/kg	Subcutaneous	Acute	Tumors at site of application		3
Rat		Intravaneous	1 Injection	Death	$LD_{50} > 200 \text{ mg/kg}$	4
Bluegill (<i>Lepomis</i> macrochirus)	:	Medium	87 hours	Death	$LC_{87}=1000~\mu g/L$	9
Mouse		Dermal	3 per week for 50 weeks	Skin tumors	LOAEL = 0.15 mg/kg-BW	\$
Rodent	2 mg/kg	Oral	Chronic	Carcinogenic		9
Mouse	1 mg	Dermal		Carcinogenic		9
Mouse	5 mg	Subcutaneous	Single	Carcinogenic	(9
Mouse	2 mg	Gavage	2 Days	Increase hepatomas and pulmonary adenomas		7
Mouse	1.5 mg/kg	Gavage	Intermittent over 5 weeks	Increase hepatomas and pulmonary adenomas		7

Benzo(a)anthracene (B(a)a) is a polycyclic aromatic hydrocarbon (PAH) which is a byproduct of incomplete combustion. B(a)a binds strongly to soil and sediment (K_w = 4.1x10³ and K_w = 2x10³). Biodegradation is slow in soils and sediment. The half-life is approximately 1 year. B(a)a is strongly adsorbed by bacteria (9). B(a)a is not expected to bioconcentrate or bi

Mouse	40 mg/kg/d	Gavage	10 days during gestation	Reduced pup weights at 20 days		2

Benzo(a)pyrene B(a)P is a polycyclic aromatic hydrocarbon (PAH) present in the environment as a byproduct of incomplete combustion. Some microbes have also demonstrated the ability to synthesize B(a)P. The majority of B(a)P present in the environment is due to releases into the atmosphere. B(a)P that deposits on land and water will partition primarily to soil and sediment, where it is very persistent (K_{ow}=1.55x10° and K_{oc}=5.5x10°). Biodegradation is the principle route of B(a)P degradation in soil and sediment. The process is slow, with a T_{1/2} of approximately 290 days (soil). B(a)P has been shown to be acutely toxic in high doses. The primary endpoint of concern is cancer. B(a)P has been shown to cause cancer in experimental animals through exposure via inhalation, dermal application and ingestion. In addition, B(a)P is a recognized genotoxic and mutagenic agent and is a suspected human carcinogen (2).

Chicken	15 ppm	Injection into developing embryo	Single injection, near term	Decreased survival rate		5

considered an important fate process; however, organisms which lack a metabolic detoxification enzyme system, namely phytoplankton, certain zooplankton, mussels (Mytilus edulis), scallops Benzo(b)fluoranthene [B(b)F] is a polycyclic aromatic hydrocarbon (PAH) that is a byproduct of incomplete combustion. In the environment, B(b)F adsorbs strongly to soil and sediment (Kow=1.15x106, Koc=5.5x105). It is considered immobile in soil. Leaching to groundwater is not expected. Bioaccumulation in vertebrate organisms is considered to be short-term and is not (Placopecten sp.), and snails (Litternia littorea), tend to accumulate PAHs (7). The high estimated Kow suggests that B(b)F will bioconcentrate appreciably in aquatic organisms. The presence of microsomal oxidase in fish suggests, however, that the PAHs, including B(b)F, will not bioconcentrate in fish due to the anticipated rapid metabolism of these compounds. (7) The major fate systemic or reproductive toxicity data is available for B(b)F. Experimental evidence exists that B(b)F is a skin carcinogen in animals following dermal application or subcutaneous injection. B(b)F of sediment-bound B(b)F is most likely biodegradation. The T12 in soil is estimated to be approximately 610 days. Volatilization from soil is not expected to be significant (7). Limited lethality, is considered a probable human carcinogen.

Bioaccumulation:

Earthworm BAF = 0.32 (6)

moving environmental waters may be important (5). B(ghi)P has the potential to bioconcentrate in aquatic systems (5). Limited toxicological data is available specific to B(ghi)P. Some evidence Benzo(g,h,i)perylene [B(ghi)P] is a polycyclic aromatic hydrocarbon (PAH), that is a byproduct of incomplete combustion. In the environment, B(ghi)P is expected to adsorb strongly to soil and organic materials in sediment (Kow = 3.2x10°, Koc = 1.6x10°). Adsorption to suspended particulate matter and sediments is an important environmental process. Movement by sediment-sorbed B(ghi)P is probably an important transport process for this compound. B(ghi)P is highly immobile in soil. (5) The half-life in aerobic soils is estimated to be approximately 600 days. Volatilization from shallow, fastexists that B(ghi)P is genotoxic. The data regarding the carcinogenicity of B(ghi)P is considered inconclusive at this time.

Bioaccumulation:

Earthworm BAF = 0.24 (4)

Environmental Fate:

- Henry's Law Constant = 1.6×10^{-6} atm m³/mol (5)
- Vapor pressure = 1.0×10^{-10} mm Hg @ 25° C (5) Water solubility = 2.6×10^{4} mg/l @ 25° C (5)

Ecological Toxicity Profile for Benzo(k)fluoranthene

Organism	Dose	Exposure Route	Exposure Period	Effect	Endpoint	Reference
			Benzo(k)fluoranthene			
	0.6 mg/injection	Subcutaneous injection	1 injection/month for 3 months	Sarcoma at site of injection		1
	5 mg/kg	Implant		Tumors at site of implant		2
		Subcutaneous		Tumors at site of injection	$TD_{Lo} = 72 \text{ mg/kg}$	е
Rodent	72 mg/kg	Oral	Chronic	Carcinogen		4

(Kow = 1.15x106, Koc = 5.5x103). Leaching from soil to groundwater can occur, especially in soils with low organic content (e.g., sand) or high porosity, or from sites htat have been exposed to spills Benzo(k)fluoranthene [B(k)F] is a polycyclic aromatic hydrocarbon (PAH) that is a byproduct of incomplete combustion. In the environment, B(k)F adsorbs strongly to soil and sediment or chemical wastes containing B(k)F. B(k)F is not expected to leach in soil under most other conditions. Volatilization from soil would probably be low due to B(k)F's low vapor pressure and strong adsorption to soil. B(k)F is not expected to volatilize significantly from the aquatic environment. (6) Lethality, systemic and reproductive toxicity data for B(k)F is limited. Experimental data that is available suggests that B(k)F is a weak carcinogen through the oral or dermal route. Studies to date also suggest that B(k)F may be genotoxic and mutagenic.

Bioaccumulation:

Earthworm BCF = 0.25(5)

Bioconcentration:

Fish Log BCF = 4.97 (6)

Environmental Fate:

- Henry's Law Constant = 4.2×10^8 atm m³/mol (6)

Daphnia magna				Death	$EC_{20} = 3.8 \ \mu g/L$	5
Fish				Death	$EC_{20} = 148 \ \mu g/L$	2

Beryllium is a naturally occurring element that is released to the environment by the weathering of rocks and soils. It is also naturally emitted to the atmosphere by windblown dusts and volcanic particles. Fuel oil and coal combustion produce significant emissions. Beryllium is not expected to bioconcentrate or biomagnify in the food chain. Limited mobility in soil is expected due to its tendency to adsorb tightly. Leaching through soil to groundwater also is not expected.

Bioconcentration:
• Fish BCF = 19 (1)

toxicity of \(\theta\)-BHC is probably due to its longer half-life in the body and its accumulation in the body with time. The excretion of BHC isomers is primarily through the urine. The primary urinary metabolites are chlorophenols and an epoxide. The conversion occurs mainly by hepatic enzymes. In mice, exposure to 64.6 mg technical grade BHC/kg/day for 3 months led to increased testicular weight and degeneration of seminiferous tubules. α-BHC, β-BHC, γ-BHC, and technical-grade BHC have been shown to be liver carcinogens in rats and mice (6). A bioconcentration γ -BHC (lindane) is the most toxic, followed by α -, δ -, and β -BHC; however, on chronic exposure β -BHC is the most toxic followed by α -, γ -, and δ -BHC. With chronic exposures, the increased Technical-grade hexachlorocyclohexane (BHC) has been shown to be well-absorbed in the gastrointestinal tract of animals. The toxicity of the isomers varies. With respect to acute exposure, factor of 1,613 has been calculated for BHC.

Bioconcentration (α-BHC):

Zebra fish steady-state BCF = 1100 (6)

Bioconcentration (β -BHC):

Zebra fish steady-state BCF = 1460 (6)

Zebra fish steady-state BCF = 1770 (6) Bioconcentration (8-BHC):

Environmental Fate (α -BHC):

 $Log K_{oc} = 3.57$

Log K., = 3.46

Henry's Law Constant = 4.8×10^{-6} atm m³/mol

Vapor Pressure at 20°C = 0.02 mm Hg

Environmental Fate (β -BHC):

 $Log K_{oc} = 3.57$ = 4.50Log K.,

Henry's Law Constant = 4.5×10^{-7} atm m³/mol

Vapor pressure at 20° C = 0.005 mm Hg

Coho salmon			96 hours	Death	$LC_{50} = 23 \ \mu g/L$	9

treatment, in forestry, and for animal treatment. EPA no longer permits the use of lindane for purposes involving direct aquatic application. Direct supervision is required for certain applications decomposition process for BHCs in soil and water. Lindane can leach from soil to groundwater, sorb to soil particles, or volatilize to the atmosphere. Lindane is bioconcentrated to high levels of lindane on livestock, structures, and domestic pets. Once released in the environment, BHCs can partition to all environmental media. Biodegredation is believed to be the dominant terrestrial and aquatic organisms. Technical-grade BHC has been shown to be well-absorbed in the gastrointestinal tract of animals. The toxicity of the isomers varies. With respect to acute Lindane is used as an insecticide and as a therapeutic scabicide, pediculocide, and ectoparasiticide for humans and animals. As an insecticide, it is used on fruit and vegetable crops, for seed following uptake from surface waters by a number of aquatic organisms. Lindane and isomers do not undergo biomagnification in terrestrial food chains to a great extent due to metabolism by exposure, y-BHC (lindane) is the most toxic, followed by \alpha., \delta., and \delta-BHC; however, chronic exposure to \delta-BHC is the most toxic, followed by \alpha., \gamma-, and \delta-BHC. With chronic exposures, the increased toxicity of \(\theta\)-BHC is probably due to its longer half-life in the body and its accumulation in the body with time. The excretion of BHC isomers is primarily through the urine. The primary urinary metabolites are chlorophenols and an epoxide. The conversion occurs mainly by hepatic enzymes. Lindane has not been reported to cause fetotoxicity in animals. In mice, exposure to 64.6 mg technical-grade BHC/kg/day for three months led to increased testicular weight and degeneration of seminiferous tubules. α-BHC, β-BHC, γ-BHC, and technical-grade-BHC have been shown to be liver carcinogens in rats and mice (1).

Bioaccumulation:

Earthworm BAF = 4.2(7)

(Continued)

Bioconcentration:

- Brine shrimp BCF (from surface water) = 183
- Rainbow trout fry BCF (from surface water) = 319
 - Pink shrimp BCF (from surface water) = 84
- Sheepshead minnow BCF (from surface water) = 490 Prawn BCF (from surface water) = 1,273

Environmental Fate:

- $Log K_{ow} = 3.3$
- Henry's Law Constant = 3.2×10^{-6} m³/mol
 - Vapor pressure = 9.4×10^{-6} mm Hg

Table 4L-11

Ecological Toxicity Profile for Chloroethane

Organism	Dose	Exposure Route	Exposure Period	Effect	Endpoint	Reference
)	Chloroethane		
Rat		Inhalation	102 weeks, 5 day/wk, 6 hours/day	Reproductive	NOAEL = 15,000 ppm	1
Mouse		Inhalation	100 weeks, 5 day/wk, 6 hours/day	Reproductive	NOAEL = 15,000 ppm	-
Mouse		Inhalation		Cancer effect level (uterus, liver, lungs)	LOAEL = 15,000	1

The high vapor pressure and volatility from water suggest that this compound would evaporate rapidity from soil sufaces and that volatilization would be a mojor removal process. The relatively low K_{oc} values for chloroethane indicate that this compound is highly mobile in soil and may undergo significant leaching (1).

Bioconcentration: • BCF = 7.5 based on K_{ow} and water solubility (1)

Environmental Fate:

Organism orthern uawfish tychocheilu:

Chrysene is one of the polycyclic aromatic hydrocarbons (PAHs). Chrysene is present in the environment due to natural and man-made sources. Combustion is the primary source of chrysene in Biodegradation ocurs in soils and sediment at a slow rate (t,, = 1,000 days). Limited toxicological data specific to chrysene is available. At relatively high concentrations, ingestion of chrysene is however, PAHs are not likely to appreciably bioconcentrate in organisms which have mucrosomal oxidase, such as fish, as this enzyme enables the organism to metabolize them. Some marine the environment. Chrysene is persistent in the environment, partitioning to soil and sediment (K_{vw} = 4.1×10², K_{vc} = 2×10², and Log K_{vw} = 5.61). The potential exists for bioaccumulation. organisms have no detectable aryl hydrocarbons hydroxylase enzyme systems, namely phytoplankton, certain zooplankton, mussels (Mytilus edulis), scallops (Placopecten sp.), and snails (Litternia fatal to rats and mice. Experiental evidence suggests that chrysene is a weak carcinogen. Moderate evidence supports the conclusion that chrysene is a skin carcinogen in experimental animals. Chrysene has been shown to be genotoxic in some test systems. The evidence is considered weakly positive. Based on the estimated BCF values, chrysene would be expected to bioconcentrate; ittorea). Those organisms which lack a metabolic detoxification system tend to accumulate PAHs. Volatilization from water should not be an important process. (5)

Bioaccumulation:

Earthworm BAF = 0.07 (4)

Bioconcentration:

- BCF = 10,816
- Water flea (Daphnia magna) BCF (after 70 hours-rapidly eliminated) ≈ 2,000 (5)

Environmental Fate:

is estimated to be approximately 18-21 days. Limited lethality and systemic or reproductive toxicity data are available for D(ah)A. D(ah)A has been shown to be carcinogenic in experimental animals Dibenz(a,h)anthracene [D(ah)A] is a polycyclic aromatic hydrocarbon (PAH) that is a byproduct of incomplete combustion. In the environment, D(ah)A adsorbs strongly to soil and sediment (K_w = 3.3×10⁶). It is considered immobile in soil and leaching to groundwater is not expected. The major fate of soil- and sediment-bound D(ah)A is biodegradation. The T₁, in soil (lung, thorax, and skin). There is sufficient evidence that D(ah)A is active in short-term genotoxicity tests. D(ah)A is expected to bioconcentrate in aquatic organisms; however, it may bioconcentrate in organisms which have microsomal oxidase, such as fish, as this enzyme enables the rapid metabolization of certain PAHs. Those organisms which lack a metabolic detoxification enzyme system, namely phytoplankton, certain zooplankton, mussels (Mytilus edulis), scallops (Placopecten sp.), and snails (Litternia littorea), tend to accumulate PAHs. Volatilization should not be an important process. (13)

Bioconcentration:

Red-tailed Hawk					NOAEL = 19.3 mg/kg/day	4

1,2-Dichloroethane does not occur naturally. It is produced commercially and used as a chemical intermediate in the production of several other chemicals as well as a lead scavenger additive to unleaded gasoline. Previously it was used in varnish and finish removers, soaps and scouring compounds, solvents, degreasers, paints, adhesives, and fumigants. Releases to surface water and soils are likely to partition rapidly to the atmosphere by volitilization. Little absorption to soil is expected. An experimental BCF of 2 indicates that the compound will not bioconcentrate in aquatic organisms or bioaccumulate in the food chain (1).

Bioconcentration:

BCF (Bluegill) = 2 (2)

ironmental Fate:

Log $K_{ow} = 1.45 - 1.48$ Vapor Pressure at $20^{\circ}C = 64 \text{ mmHg}$

Rainbow trout		Medium	96 hour static	Death	$LC_{50} = 1.6 \mu g/L$	2
Freshwater aquatic organism		All isomers	Chronic	Protection of aquatic life	AWQC = 0.0056 ug/L	8
Freshwater fish (Channa puncutata)		Medium	96 hour		$LC_{50} = 0.16 \text{ ppb (Endosulfan I)}$ $LC_{50} = 4.8 \text{ ppb (tech)}$ $LC_{50} = 6.6 \text{ ppb (Endosulfan II)}$	
Carp (Cirrhinus mrigrala)			96 hour		$LC_{50} = 0.6$ ppb (Endosulfan I) $LC_{50} = 1.3$ ppb (tech) $LC_{50} = 8.8$ ppb (Endosulfan II)	
Saltwater aquatic organism		All isomers	Chronic	Protection of aquatic life	AWQC = 0.0087 ug/L	8

Table 4L-19

Organism	Dose	Exposure Route	Exposure Period	Effect	Endpoint	Reference
		End	osulfan, Endosu	Endosulfan, Endosulfan I, II, and Endosulfan Sulfate	Sulfate	
Japanese quail		Egg immersed 30 sec.	Observed 15- 17 days	Embryonic mortality	0.1 g/L	·
Mallard		Oral		Acute	$LD_{50} = 205-245 \text{ mg/kg}$	4
Ring-necked pheasant		Oral		Acute	LD ₅₀ = 620-1,000 mg/kg	4
Meadow vole		Endosulfan			NOAEL = 0.29 mg/kg/day	6
Red fox		Endosulfan			NOAEL = 0.065 mg/kg/day	6
American Robin		Endosulfan			NOAEL = 17.22 mg/kg/day	6
Great Blue Heron		Endosulfan			NOAEL = 5.54 mg/kg/day	6
Cooper's hawk		Endosulfan			NOAEL = 9.69 mg/kg/day	6
Red-tailed hawk		Endosulfan			NOAEL = 7.10 mg/kg/day	6

Endosulfan is registered in the United States and is widely used as a contact and stomach insecticide on over 60 food and non-food crops. Pure endosulfan may be found as two different which has similar chemical properities to the pure substance, results from endosulfan's photolysis, biotransformation, or oxidation. Both endosulfan isomers can be readily metabolized to endosulfan Endosulfan does not bioaccumulate to high levels in terrestrial or aquatic systems. In aquatic systems, residue levels in fish generally peak within 7 days to 2 weeks after continuous exposure conformations: \alpha, or I, and \beta, or II. Technical grade endosulfan consists mainly of these isomers as well as a few impurities and degradation products. One of these products, endosulfan sulfate, sulfate by a variety of organisms. Endosulfan has been released into the environment mainly as a result of its use as an insecticide. There are no known natural sources of the compound. (3) to endosulfan. In terrestrial systems, endosulfan generally is not translocated in plant tissues (1). Endosulfan does not appear to biomagnify in the food chain. No toxicity information was found for the environmental fate specific to the isomers of endosulfan sulfate.

Bioconcentration (Endosulfan):

- BCF $\leq 3,000$
- Mussel BCF = 600, 22.5
- Striped mullet BCF = 2,755(1)

Bioconcentration (Endosulfan I);

(Continued)

 $Log~K_{\infty} = 3.5$

Environmental Fate (Endosulfan):

- Log Kow = 3.55, 3.62
- Henry's Law Constant = 1.0×10^{-5} atm m³/mol @ 25°C
 - Vapor Pressure = 1×10⁻⁵ mm Hg @ 25°C
 - Water Solubility = 0.16-0.15 ppm @ 22°C

Environmental Fate (Endosulfan I):

- Log Kow = 3.83, 3.55
- Henry's Law Constant = 1.0×10⁻⁵ atm m³/mol @ 25°C
 - Vapor Pressure = 1×10^{-5} mm Hg @ 25° C
 - Water Solubility = 0.32 ppm @ 22°C

Environmental Fate (Endosulfan II):

- Log Kow = 3.52
- Henry's Law Constant = 1.91×10^{-5} atm m³/mol @ 25°C
 - Vapor Pressure = 1×10⁻⁵ mm Hg @ 25°C
 - Water Solubility = 0.33 ppm @ 22°C

Environmental Fate (Endosulfan sulfate):

- $Log K_{ow} = 3.66$
- Henry's Law Constant = 2.6×10^5 atm m³/mol @ 25° C
 - Vapor Pressure = 1×10⁻⁵ mm Hg @ 25°C
- Water Solubility = 0.22 ppm @ 22°C

Guppy (Poecilla reticulata)		Medium	96 hr	Death	$LC_{so} = 97.1 \text{ mg/L}$	∞
Fathead minnow (Pimephales promelas)		Medium - static	96 hr	Death	$LC_{so} = 42.3 \text{ mg/L}$	6
Coho salmon (Oncorhynchus kisutch)		Medium - static	24 hr	Death	$LC_{100} = 50.0 \text{ mg/L}$	6

(Continued)

Ethylbenzene is an aromatic hydrocarbon present in crude petroleum. The physicochemical properties of ethylbenzene reveal a strong tendency for it to partition to the atmosphere. The log K_{cw} of ethylbenzene indicates that there is a good possibility of its adsorption to soil. Sorption and retardation by soil organic carbon will occur to a small extent, but sorption is not significant enough to prevent migration in most soils. Ethylbenzene does not significantly bioaccumulate. Biodegradation of this compound occurs by aerobic soil microbes. In surface water, transformation may occur through oxidation and biodegradation (5).

Bioconcentration:

- Clam BCF = 4.7 (6)
- Clam log BCF = 0.67
- Fish BCF = 37.5 (based on log Kow)
 - Fish log BCF = 2.16
- Goldfish log BCF = 1.9

Environmental fate:

- $Log K_{ow} = 3.15$
- Henry's Law Constant = 8.44×10^{-3} atm m³/mol
 - Vapor Pressure = 7 mm Hg @ 20°C

Table 4L-21

Ecological Toxicity Profile for Fluoranthene

Organism	Dose	Exposure Route	Exposure Period	Effect	Endpoint	Reference
			Fluoranthene			
Rat		Oral		Death	$LD_{50} = 2,000 \text{ mg/kg}$	1
Mouse		Interveneous injection		Death	$LD_{so} = 2 \text{ gm/kg}$	_
Mouse	3.5 mg/mouse			Increase in lung tumor incidence		2
Rabbit		Dermal	Not specified	Death	$LD_{50} = 3.18 \text{ gm/kg/24 hr}$	3
Bluegill		Medium	96 hour	Death	$LC_{50} = 3,980 \text{ ug/L}$	4
Sheepshead minnow		Medium	96 hour	Death	LC ₅₀ = 560 mg/L	4
Mysid shrimp		Medium - static	96 hour	Death	$LC_{so} = 40 \text{ ug/L}$	5
Polychaete		Medium - static	96 hour	Death	$LC_{s0} = 500 \text{ mg/L}$	5
Alga (Skeletonima costatum)		Medium - static	96 hour	reduced cell numbers	EC ₅₀ = 45 mg/L	5

Fluoranthrene is a polycyclic aromatic hydrocarbon (PAH) that is a byproduct of incomplete combustion. In the environment, fluoranthrene adsorbs strongly to soil and would be expected to remain bound in the upper layers of soil ($K_{ow} = 7.9 \times 10^4$, $K_{ow} = 3.8 \times 10^3$). Fluoranthene degrades slowly in soil ($t_{1/2} = 5$ months - 2 years). The bioconcentration factor as determined in rainbow trout indicates the potential for bioconcentration in aquatic species (Log BCF = 2.58). Limited toxicity data is available for fluoranthene.

Bioaccumulation:
• Earthworm BAF = 0.08 (6)

(Continued)

Bioconcentration:
• Rainbow trout BCF (liver) = 379

Channel catfish (Ictalurus punctatus)		Medium - static	96 hours as heptachlor	Death	$LC_{50} = 25 \ \mu g/L$	7
Sheepshead minnow (Cyprinodon Variegatus)		Medium (saltwater), flow- through	96 hours as heptachlor	Death	$LC_{50} = 10.5 \ \mu g/L$	7

(Continued)

log soil organic carbon adsorption coefficient (log Kw) for heptachlor is estimated to be 4.34. The log Kw for heptachlor epoxide is estimated to range between 3.34 and 4.37. These log Kw values indicate epoxide are described together because 20% of heptachlor is changed within hours into heptachlor epoxide in the environment and in living systems such as animals or humans by microsomal enzymes. The bottom sediment. Heptachlor and heptachlor epoxide are taken up by plants through the roots. The logarithm of the n-octanol/water partition coefficient (log K_w.) for heptachlor is 5.44 and for heptachlor Biomagnification of heptachlor is not significant since heptachlor is metabolized to heptachlor epoxide readily by higher trophic levels. Because of the more persistent nature of heptachlor epoxide and its Heptachlor is a man-made chemical that was used for killing insects in homes, buildings and on food crops. There are no natural sources of heptachlor or heptachlor epoxide. Heptachlor and heptachlor lipophilicity, biomagnification of heptachlor epoxide in terrestrial food chains is significant. Animals that ingested heptachlor in food before and/or during gestation had smaller litters, some offspring had factor affecting mobility. Heptachlor and heptachlor epoxide are less likely to leach from soil with a high organic matter content. If released into water, then they will adsorb strongly to suspended and epoxide is 5.40, indicating a high potential for bioconcentration and biomagnification in the food chain. A bioconcentration factor (BCF) of 20 has been calculated. A bioaccumulation factor (BAF) for The organic matter content of the soil is another damaged eyes, and some offspring did not survive long after birth. Infertility was also observed in studies with rats and mice. Lifetime exposure to heptachlor resulted in liver tumors (1). Heptachlor epoxide does not thin American kestrel eggs. These findings are in agreement with earlier studies of Canada geese. The presence of heptachlor epoxide in kestrel eggs, however, indicates food chain earthworms for heptachlor epoxide has been calculated to be 10 (8). Heptachlor epoxide is more harmful than heptachlor, primarily because of its ability to be stored in fat for long periods of time. a very high sorption tendency, suggesting that these compounds will adsorb strongly to soil and are not likely to leach into groundwater in most cases. contamination (3).

Bioaccumulation (Heptachlor epoxide):
• Earthworm BAF = 10 (8)

Bioconcentration (Heptachlor):

BCF = 9500 (9)

Bioconcentration (Heptachlor epoxide):

BCF = 4500 (9)

(Continued)

Environmental Fate (Heptachlor):

Log K_w = 4.34

Log K., = 5.44

Environmental Fate (Heptachlor epoxide):

 $Log K_{ov} = 3.34-4.37$ $Log K_{ow} = 5.40$

Ecological Toxicity Profile for Indeno(1,2,3 cd)pyrene

Organism	Dose	Exposure Route	Exposure Period	Effect	Endpoint	Reference
			Indeno(1,2,3-cd)pyrene	9		
Mouse		Skin	20 Days	Tumors	$TD_{L0} = 40 \text{ mg/kg}$	1
Mouse	0.6 mg	Subcutaneous	1 time per month for Sarcomas 265 days	Sarcomas		2
Rat	4.15 mg/kg	Implant		Tumors; lung and thorax		3
Rodent	72 mg/kg-BW	Oral	Chronic	Carcinogen		4

Indeno(1,2,3-CD)pyrene [I(1,2,3-CD)P] is a polycyclic aromatic hydrocarbon (PAH) that is a byproduct of incomplete combustion. In environment, I(1,2,3-CD)P adsorbs strongly to soil and sediment animals via ingestion. Data is inconclusive regarding carcinogenic potential by dermal exposure. Some evidence of genotoxicity is also indicated. I(1,2,3-CD)P shows a strong potential for bioconcentration; however, PAHs are not likely to appreciably bioconcentrate in organisms that have microsomal oxidase, such as fish, since this enzyme enables the organism to metabolize PAHs tend to accumulate PAHs (6). Bioaccumulation, especially in vertebrate organisms, is considered to be short-term, and is not considered an important fate process (6). Volatilization from water will (Kor = 3.2x10°, Kor = 1.6x10°). Lethality and systemic and reproductive toxicity data for I(1,2,3-CD)P is limited. Experimental evidence suggests that I(1,2,3-CD)P is carcinogenic to experimental (6). Those organisms lacking a metabolic detoxification enzyme system, namely phytoplankton, certain zooplankton, mussels (Mytilus edulis), scallops (Placopecten sp.), and snails (Litternia littorea), probably not be an important transport process (6).

Bioaccumulation:

Earthworm BAF = 0.42(5)

Bioconcentration:

BCF = 59,407 (6)

Environmental Fate:

- Henry's Law Constant = 5.89×10^{-10} atm m³/mol (6)
 - Vapor Pressure = 1.0×10^{-10} mm Hg (6)
 - Water Solubility = 0.062 mg/L (6)

Fathead minnow		Medium	96 hours as PbCl ₃	Death	$LC_{50} = 5.58 \text{ ppm}$	10
Mallard	6-8 mg/kg/day as lead nitrate		*	Lowered hematocrit and hemoglobin concentration		11
Meadow vole	As lead nitrate				NOAEL = 15.86 mg/kg/day	15
Red fox	As lead nitrate				NOAEL = 3.44 mg/kgday	15
Earthworm					LC ₅₀ = 3,000 mg/kg ⁻¹	17
Terrestrial plant		Soil		20% reduction in plant growth	50 mg/kg	15

Lead is ubiquitous and is a characteristic trace constituent in rocks, soils, water, plants, animals and air. More than 4 million metric tons of lead are produced worldwide each year, mostly for the The widespread broadcasting of lead through anthropogenic activities, especially during the past 40 years, has resulted in an increase in lead residues throughout the environment. Lead is neither essential nor beneficial to living organisms and is toxic in most of its chemical forms. Excessive amounts of lead can cause growth inhibition in plants, as well as reduced photosynthesis, mitosis, and water absorption. In domestic and experimental animals, lead adversely affects weight, survival, behavior, litter size, and skeletal development, and induces teratogenic and carcinogenic responses in some species. Lead chemistry is complex. In water, lead is most soluble and bioavailable under conditions of low pH, low organic content, low concentrations of suspended sediments, and low concentrations of salts of calcium, iron, manganese, zinc, and cadmium (3). Models of lead speciation combined manufacture of storage batteries, gasoline additives, pigments, alloys, and ammunition.

(Continued)

Although mobility through soils to waters, both surface and groundwater, is not a major route of environmental exposure, exposure to the fetus. Lead is an accumulative metabolic poison that affects behavior and the hematopoietic, vascular, nervous, renal, and reproductive systems. In general, organo-lead compounds are more with toxicity changes in the cell membrane predict that lead is more toxic at lower pH (4). Likewise for soils, mobility is dependent on factors such as pH, organic content, presence of inorganic lead-bearing soil particles either by ingestion or inhalation can be a route of exposure. Lead can be incorporated into the body by inhalation, ingestion, dermal absorption, and placental transfer toxic than inorganic lead compounds, food chain biomagnification is negligible, and younger, more immature organisms are most susceptible (3). Although lead does not biomagnify, its concentration in aquatic and terrestrial vertebrates tends to increase with the age of the animal. Distribution of lead is localized in hard tissues, such as bones and teeth (6). Ingestion of lead shot from hunter-killed or crippled waterfowl appears to be the major source of lead exposure to bald eagles. Alternatively, ospreys do not ingest those items which contain lead shot or hard tissues that have accumulated lead (7). The proposed lead criteria for the protection of natural resources and human health recommends for the mouse a daily total intake > 0.05 mg/kg and for the mule deer total intake > 3 mg/day (3). Accumulation of lead with age has been reported in the pronghorn antelope, but the mule deer did not show accumulation in the same study. Background levels of lead in the livers and kidneys from mule deer and pronghorn antelope range from 0.6 to 0.9 µg/g (freeze-dried weight) (8). Lead concentrations of > 10 µg/g have been associated with diagnostic lead toxicosis in experimental mammals; however, mammals with behavioral and physiological signs of lead intoxication have died with < 5 µg/g (9). Plants and animals may bioconcentrate lead, but biomagnification has not been detected. Older organisms tend to contain the greatest body burden of lead. In aquatic organisms, lead concentrations are usually highest in benthic organisms and algae, and lowest in upper colloids and iron oxides, and ion-exchange characteristics (2). rophic level predators such as carnivorous fish (2).

Bioaccumulation:

Earthworm BAF = 0.66 (16)

Bioconcentration:

- Oyster BCF = 6600 (14)
- Alga BCF = 92,000 (14)
- Rainbow trout BCF = 726 (14)
 - Fish BCF = 42(3)
- Insect BCF = 500 (3)
- Oyster BCF = 536(3)Alga BCF = 725(3)

Table 4L-25

Ecological Toxicity Profile for 2-methylnaphthalene

Organism	Dose	Exposure Route	Exposure Period	Effect	Endpoint	Reference
			2-Methylnaphthalene	ene		
Rat	5 mg/kg	Oral		Lethal		1
Rat		Oral		Death	$LD_{50} = 1,630 \text{ mg/kg}$	2
Rat		Feed	700 days, 6 days/week		NOAEL = 41 mg/kg/day	9
Mice	400 mg/kg	Intraperitoneal injection	Single dose	Complete exfoliation of bronchiolar epithelium		3
Mouse	1,000 mg/kg	Intraperitoneal injection	Single dose	20-40% lethality		3
Grass shrimp		Medium	96 hours	Death	$LC_{s0} = 1100 \ \mu g / L$	4
Sheepshead minnow		Medium	96 hours	Death	$LC_{50} = 2000 \ \mu g/L$	4
Dungeness Crab		Medium	48 hours	Death	LC ₅₀ = 5.0 mg/L	5
Dungeness Crab		Medium	96 hours	Death	LC ₅₀ = 1.3 mg/L	5

2-Methylnapthalene (2-MN) is a polycyclic aromatic hydrocarbon (PAH) that is a component of crude oil and a byproduct of combustion. 2-MN adsorbs strongly to soils and is considered innuobile in soils (Log K_{ow} = 3.86, K_{co} = 8.5×10³). Volatilization and biodegradation are the principle removal mechanisms for 2-MN from soils and surface water. Toxicological data for 2-MN is limited and somewhat contradictory.

Bioconentration:

Crustacean BCF = 967-1625 (dimethylnaphthalenes)

Table 4L-26

Ecological Toxicity Profile for Phenanthrene

Organism	Dose	Exposure Route	Exposure Period	Effect	Endpoint	Reference
			Phenanthrene			
Mouse		Oral	Not specified	Death	$LD_{50} = 700 \text{ mg/kg}$	1
Mouse	71 mg/kg	Applied to skin	Not specified	Tumor formation at site of application	Not specified	2
Mallard	4,000 mg/kg in diet (PAH mixture)	Oral	7 months	Increased liver weight and hepatic blood flow	Not specified	6
Grass shrimp		Medium	24 hour	Death	$LC_{50} = 370 \text{ ug/L}$	3
Sandworm		Medium	96 hour	Death	$LC_{50} = 600 \text{ ug/L}$	3
Freshwater aquatic organism			Chronic	Proposed AWQC - protection of aquatic life	LOEL = 6.3 ug/L	5
Saltwater aquatic organism			Chronic	Proposed AWQC - protection of aquatic life	LOEL = 4.6 ug/L	5
Mouse		Intravenous injection	Not specified	Death	$LD_{50} = mg/Kg$	4
Rat	150 mg/kg-BW	Intraperitoneal injection	Not specified	Changes in blood chemistry and nephrotoxicity	Not Specified	9

Phenanthrene is a polycyclic aromatic hydrocarbon (PAH) that is a byproduct of incomplete combustion. In the environment, phenanthrene adsorbs strongly to soil and sediment and is considered to be relatively immobile. Volatilization from water and soil is not expected to be significant, since most of the phenanthrene is expected to be adsorbed (7). It is not expected to leach to groundwater. Phenanthrene has tested negative as a complete carcinogen. Significant bioconcentration should occur in aquatic organisms. By the action of microsomal oxidase, however, fish are capable of rapidly metabolizing PAHs. Phananthrene is expected to be similarly degraded in fish, and therefore may not bioconcentrate significantly. (7) Some marine organisms have no aryl hydrocarbons hydroxylase

4L-56

(Continued)

enzyme systems, namely phytoplankton, certain zooplankton, mussels (Mytilus edulis), scallops (Placopecten sp.), and snails (Litternia littorea). Those organisms which lack a metabolic detoxification enzyme system tend to accumulate PAHs. (7)

Bioaccumualtion:

Earthworm BCF = 0.12 (6)

Bioconcentration:

- Clam (24 hrs.) BCF = 32 (3)
- Daphnia pulex (24 hrs.) BCF = 325 (3)

Environmental Fate:

- $K_{\infty} = 1.4 \times 10^4$
- $Log K_{oc} = 4.36 (7)$
 - $K_{ow} = 2.4 \times 10^4$
- $\label{eq:constraint} \mbox{Log } K_{\rm cw} = 4.57 \; (7) \\ \mbox{Henry's Law Constant} = 1.24 \times 10^4 \; \mbox{atm m}^3/\mbox{mol} \; (7)$
 - Vapor pressure = 6.80×10^4 mm Hg (7)
 - Water solubility = 1.29 mg/L (7)

Table 4L-27

Ecological Toxicity Profile for Pyrene

Organism	Dose	Exposure Route	Exposure Period	Effect	Endpoint	Reference
			Pyrene			
Guinea pig	5 mmol	Dermal	Single dose	Phototoxic when subsequently exposed to UV light.		-
Rat, Mouse	50-90 ug/m3	Inhalation	22 months	Lung neoplasia 10x above controls.		2
Mosquito fish		Medium	96 hr	Death	TLm = 0.0026 mg/L	3
Rat		Oral	Acute	Death	$LD_{50} = 2,700$ mg/Kg	4
Mouse		Oral	Acute	Death	$LD_{so} = 800 \text{ mg/Kg}$	4
Mouse	10 % pyrene solution	Applied to skin	Lifetime	No skin tumors		9
Mouse		IP injection	Single	Death	$LD_{50} = 680 \text{ Kg-BW}$	9
Rat	150 mg/kg	IP injection	Single	Altered blood chemistry and nephrotoxicity		ν
Mouse	127 mg/kg	Oral-Food	25 Days	Dialation of renal tubules		9

Pyrene is a polycyclic aromatic hydrocarbon (PAH) that is a byproduct of incomplete combustion. In the environment, pyrene adsorbs strongly to soil and sediment. It is not expected to leach to groundwater and will not hydrolyze or evaporate significantly. Laboratory tests with soil microbes indicate probable biodegradation. Bioaccumulation, especially in vertebrate organisms, is not considered an important fate process. Minimal to moderate bioconcentration of pyrene in aquatic ecosystems would be expected. Some marine organisms have no detectable aryl oxidase hydrocarbons hydroxylase enzyme systems, namely phytoplankton, certain zooplankton, mussels (Mytilus edulis), scallops (Placopecten sp.), and snails (Litternia littorea). Those organisms which lack a metabolic detoxification enzyme system tend to accumulate PAHs. (8) Pyrene has been shown to be acutely toxic at high doses. Evidence suggests that pyrene may be slightly genotoxic. Pyrene is a questionable carcinogen.
